Acknowledgments

The 2005 Environmental Sustainability Index (ESI) was made possible by generous external support from the Coca-Cola Foundation, the Samuel Family Foundation, and George Kailis.

The final version of the 2005 ESI benefited from the expertise, advice, and comments of the participants in an Expert Workshop that took place on 9-10 December 2004, at Yale University. The ESI team (from Yale, CIESIN, the JRC, and the World Economic Forum) gratefully acknowledges the contributions of: Neric Acosta, Bob Chen, Young-Keun Chung, Tomas Hak, Kirk Hamilton, Alan Hecht, Anders Hoffman, Michael Ma, Jeff McNeely, Charles Ian McNeill, Rosemary Montgomery, Heekyong Noh, John O'Connor, Tom Parris, Laszlo Pinter, Louise Rickard, N. Phillip Ross, and Ulrich Wieland.

A number of other people provided advice, support, analysis, data, or technical expertise. In this regard, we thank: Kym Anderson, Liliana Andonova, Timothy Boucher, Lisa Bürgi, Olivier Cattaneo, Thomas Cottier, William Davey, Carmen Dominguez, Richard Elin, Jay Emerson, Dave Ervin, John Finn, Andy Fraser, Tom Graedel, Timothy Gregoire, Ashok Gulati, Dale Hathaway, Sebastian Herrors, Kelly Hodgson, Jonathan Hoekstra, Gary Horlick, Eszter Horvath, Gary Hufbauer, John Jackson, Lee Ann Jackson, Alejandro Jara, Michael Jenkins, Tim Josling, Andrzej Kwiecinski, Wilfred Legg, Patrick Low, Arvind Panagariya, Craig Pratt, Richard Robarts, C. Ford Runge, Gary Sampson, Jeff Schott, Kerstin Schulze, Gus Speth, and Xiaoshi Xing.

Finally, the authors would like to thank the many officials in national statistical and environment ministries for their participation in the ESI country data review. Their help improved the ESI data matrix and helped to hone the ESI methodological approach.

Executive Summary

The Environmental Sustainability Index (ESI) benchmarks the ability of nations to protect the environment over the next several decades. It does so by integrating 76 data sets – tracking natural resource endowments, past and present pollution levels, environmental management efforts, and the capacity of a society to improve its environmental performance – into 21 indicators of environmental sustainability. These indicators permit comparison across a range of issues that fall into the following five broad categories:

- Environmental Systems
- Reducing Environmental Stresses
- Reducing Human Vulnerability to Environmental Stresses
- Societal and Institutional Capacity to Respond to Environmental Challenges
- Global Stewardship

The indicators and variables on which they are constructed build on the well-established "Pressure-State-Response" environmental pol-The issues incorporated and icv model. variables used were chosen through an extensive review of the environmental literature, assessment of available data, rigorous analysis, and broad-based consultation with policymakers, scientists, and indicator experts. While they do not provide a definitive vision of sustainability, the collection of indicators and variables that form the 2005 ESI provide: (1) a powerful tool for putting environmental decisionmaking on firmer analytical footing (2) an alternative to GDP and the Human Development Index for gauging country progress, and (3) a useful mechanism for benchmarking environmental performance.

The higher a country's ESI score, the better positioned it is to maintain favorable environmental conditions into the future. The five highest-ranking countries are Finland, Norway, Uruguay, Sweden, and Iceland – all countries that have substantial natural resource endowments and low population density. Each has managed the challenges of development with some success.

The lowest ranking countries are North Korea, Iraq, Taiwan, Turkmenistan, and Uzbekistan. These countries face numerous issues, both natural and manmade, and have not managed their policy choices well.

While absolute measures of sustainability remain elusive, many aspects of environmental sustainability can be measured at least in relative terms. National positions on various important elements of environmental stewardship can therefore be determined and are instructive.

The key results and conclusions that emerge from the 2005 ESI can be summarized as follows:

- The ESI has proven to be a useful gauge of national environmental stewardship. It provides a valuable summary measure of environmental performance and a counterpart to yardsticks of human development and economic wellbeing. Any measure of sustainability will have shortcomings given the significant gaps in critical data sets, divergent views about what comprises sustainability, and differing opinions about how best to address underlying uncertainties.
- Environmental sustainability is a fundamentally multi-dimensional concept. Some environmental challenges arise from development and industrialization – natural resource depletion (especially of nonrenewable resources), pollution, and ecosystem destruction. Other challenges are a function of underdevelopment and poverty-induced short-term thinking – resource depletion (especially of potentially renewable resources such as forests and water) and lack of investment in capacity and infrastructure committed to pollution control and ecosystem protection.

- There are significant differences across countries in both current environmental results and probable longer-term trends. By assembling a broad array of data that make cross-country comparisons possible, the ESI provides a powerful tool for tracking environmental performance, identifying leaders and laggards on an issue-by-issue basis, and designing policy responses.
- Most countries do well on some issues and much less well on others. Virtually no nation scores very high or very low on all 21 indicators. Thus, every society has something to learn from benchmarking its environmental performance against relevant peer countries.
- Environmental sustainability entails issues that are local as well as national and global in scale, all of which should figure in international comparisons (as they do in the ESI).
- The ESI and its elements provide a foundation for more data-driven environmental analysis and decisionmaking. In doing so, it sheds light on a number of critical issues. The ESI demonstrates, for example, that income contributes to the potential for strong environmental stewardship, but does not guarantee it. Indeed, it is striking how many of the bottom rungs of ESI are occupied by countries that are relatively wealthy.
- The relationship between environmental sustainability and economic development is complex. At every level of income, countries face environmental challenges. Some countries manage their pollution control and natural resource management challenges relatively well while others do not. Development status is therefore not environmental destiny.

- The ESI suggests that a more quantitative and systematic approach to environmental policymaking – where: (a) problems are tracked through a carefully constructed set of metrics and indicators (b) policy progress is evaluated empirically, and (c) governments benchmark their results against a relevant peer group – can help to highlight superior environmental programs, technologies, strategies, and approaches.
- ESI-based analysis reveals some of the critical determinants of environmental performance: low population density, economic vitality, and quality of governance. Some of these variables have long been identified as theoretically important. The ESI provides empirical support for these theories.
- Serious and persistent data gaps plague the ESI and other efforts to shift pollution control and natural resource management onto more analytically rigorous underpinnings. Investment at the local, national, and global scales in a more complete set of key indicators should be seen as a fundamental policy priority. The ESI does not cover a number of important issues e.g., quality of waste management, wetlands destruction, and exposure to heavy metals such as lead and mercury because the requisite data are not collected or are not reported on a basis that permits cross-country comparisons.
- The need for improved data to undergird better environmental policymaking emerges especially strongly in the developing world in the context of worldwide efforts to achieve the large-scale environmental aims of the Millennium Development Goals.

2005 Environmental Sustainability Index Report

This page is intentionally blank.

Chapter 1 – The Need for an Environmental Sustainability Index

We live in an era of numbers. In many realms, decisionmaking has become increasingly data-driven. But the environmental domain has curiously lagged in this regard. Plagued by widespread information gaps and uncertainties, environmental policymaking has often been based on generalized observations, best guesses, and "expert opinion" – or, worse yet, rhetoric and emotion (Esty 2002).

This report presents the 2005 Environmental Sustainability Index (ESI), which provides a composite profile of national environmental stewardship based on a compilation of 21 indicators that derive from 76 underlying data sets. The ESI offers a tool for shifting pollution control and natural resource management onto firmer analytic underpinnings. In this regard, the heart of the ESI is not the rankings but rather the underlying indicators and variables. By facilitating comparative analysis across national jurisdictions, these metrics provide a mechanism for making environmental management more quantitative, empirically grounded, and systematic.

This report demonstrates how a commitment to environmental indicators and greater emphasis on statistical analysis might strengthen environmental problem solving at the national policy level. The ESI, though still under development and impaired by persistent data gaps in both basic environmental monitoring data and more advanced metrics, illustrates the potential of such a policy tool. The same approach could enhance decisionmaking at the global scale, the local level, in corporations, and even within households. The lack of information on many critical issues, limited data coverage, and the noncomparability of data across countries all render the design of indices more difficult and implicitly influence what gets measured.

The selection of the 21 indicators and their underlying variables is the result of careful screening of available data sources combined with innovative approaches to designing alternative measures and "proxies" for important issues where routine monitoring does not exist and metrics are not available. Although imperfect, the ESI helps to fill a long-existing gap in environmental performance evaluation. It offers a small step toward a more vigorous and quantitative approach to environmental decisionmaking.

Just as companies have long benchmarked their performance against industry peers, national governments are finding it useful to compare their performance against others who are similarly situated, and the ESI makes such "peer group" comparisons relatively easy to do. The overall rankings must be taken for what they are -a relative and approximate indication of how close a country is to being on a sustainable environmental trajectory based on a "snapshot" view of a range of widely recognized issues including pollution control, natural resource management, and societal problem solving capacities. The real value of the ESI therefore emerges from looking at the relative position of each country on the 21 underlying indicators. In fact, given the "noise" in the analysis, we cannot really be sure that Finland outranks Norway overall. But we can say with some confidence that both of these countries are outperforming the United States and France in important aspects of environmental policy.

The most important function of the Environmental Sustainability Index is as a policy tool for identifying issues that deserve greater attention within national environmental protection programs and across societies more generally. The Environmental Sustainability Index also provides a way of identifying those governments that are at the leading edge with regard to any particular issue. This information is useful in identifying "best practices" and may help to guide thinking on what it will take to make policy progress.

The analysis of best practices and successful environmental policy does not imply that only one way towards sustainability exists. Countries face an array of issues and policy

questions when trying to improve their environmental performance. The answers that make sense will depend on the nation's specific environmental, economic, and social circumstances, internal factors such as the priority given to environmental issues as well as a multitude of external factors including the environmental policies of neighboring countries. Each policy choice must be formulated and evaluated within this context. The ESI can assist in this analytical process by identifying (a) the most significant issues a country faces (b) similar countries that have successfully addressed those issues, and (c) the trade-offs that can be expected as a result of suboptimal environmental choices.

The ESI provides a useful national policymaker's guide to pollution control and natural resource management challenges, highlighting where each particular country might find that marginal investments of funding and political attention could best be deployed. Objective measures of policy performance are an important mechanism for budget rationalization and priority setting.

The ESI takes seriously the need to track a full range of pollution and natural resource management issues that are critical to a human-centered measure of environmental wellbeing. It incorporates issues that are local in scope as well as those that are global in scale. While countries at different levels of development and with diverse national priorities may choose to focus on different elements of environmental sustainability, all of the issues included in the ESI are of relevance to all countries. The broad scope of the ESI with its strong emphasis on fundamental issues such as air pollution, water quality, and human alterations of terrestrial ecosystems - has won praise in the developing world because it features basic environmental needs and not just those of concern to developed countries.

The overall ESI scores and rankings also help to ensure that countries are graded not only on their economic results (e.g., GDP growth or competitiveness rankings) but also on other policy goals including environmental performance. In this regard, it is striking how many of the bottom rungs on the ESI are occupied by countries that are relatively wealthy.

The ESI also provides a tool for achieving global-scale policy goals. The Millennium Declaration and the related Millennium Development Goals (MDGs) explicitly commit the world community to making progress in achieving environmental sustainability within the context of a broader global agenda aimed at reducing poverty, malnutrition, and expanding education and health care (UN 2000). Moreover, donor countries supporting the MDG process increasingly insist upon accountability and transparency in how their money is spent – and the evaluation of which investments are paying off and which are not.

Some MDGs have well-established metrics that allow progress on these goals to be tracked. Goal 7 of the MDGs aims at "Ensuring Environmental Sustainability" but lacks the breadth of indicators needed to adequately gauge progress toward this ambitious goal because no such set of appropriate metrics is readily available. The ESI offers a starting point for developing such a set of metrics.

In all these regards, context matters. The ESI, with its emphasis on relative rankings, provides a mechanism for establishing context and for understanding what is possible in terms of policy progress. Indeed, it turns out the comparisons to relevant peer countries are particularly important in goal setting, identifying best practices in both policymaking and technology adoption, and spurring competitive pressure for improved performance.

Decisionmakers are eager for tools that will help them to identify problems, track trends, set priorities, understand policy tradeoffs and synergies, target environmental investments, evaluate programs, and focus limited political attention. The ESI is such a tool.

Countries want to be seen as doing well in comparison to those similarly situated. Establishing the right peer groups is thus a critical element of any benchmarking exercise. In support of this quest, we offer a series of potentially relevant groupings in Tables 2 through 8.

RANK	Country	ESI	RANK	Country	ESI	RANK	Country	ESI

Chapter 2 – Our Approach

Measuring Sustainability

Sustainability is a characteristic of dynamic systems that maintain themselves over time; it is not a fixed endpoint that can be defined. Environmental sustainability refers to the long-term maintenance of valued environmental resources in an evolving human context.

The best way to define and measure sustainability is contested. Economists often emphasize an accounting approach that focuses on the maintenance of capital stocks. Some in the environmental realm focus on natural resource depletion and whether the current rates of resource use can be sustained into the distant future.

Our emphasis is broader, more policyoriented, and shorter term. The Environmental Sustainability Index (ESI) provides a gauge of a society's natural resource endowments and environmental history, pollution stocks and flows, and resource extraction rates as well as institutional mechanisms and abilities to change future pollution and resource use trajectories.

The ESI Framework

In seeking to provide a policy-relevant gauge of national environmental conditions and their likely trajectory over the next several decades, the ESI centers on the state of environmental systems, both natural and managed. It also measures stresses on those systems, including natural resource depletion and pollution rates, because the magnitude of such stresses serve as a useful indicator of the pressure on the underlying systems. The ESI further measures impacts and responses and human vulnerability to environmental change. In addition, the ESI tracks a society's capacity to cope with environmental stresses and each country's contribution to global stewardship.

These five core components and the logic for their inclusion in the ESI are laid out in Table 9.

This basic model builds on a broad base of theory in the ecological sciences and environmental policy. The core components of the ESI have a great deal of overlap with the widely used Pressure-State-Response (PSR) indicator model, and especially its more recent

Component	Logic
Environmental Systems	A country is more likely to be environmentally sustainable to the extent that its vital environmental systems are maintained at healthy levels, and to the extent to which levels are improving rather than deteriorating.
Reducing Environmental Stresses	A country is more likely to be environmentally sustainable if the levels of an- thropogenic stress are low enough to engender no demonstrable harm to its environmental systems.
Reducing Human Vulnerability	A country is more likely to be environmentally sustainable to the extent that people and social systems are not vulnerable to environmental disturbances that affect basic human wellbeing; becoming less vulnerable is a sign that a society is on a track to greater sustainability.
Social and Institutional Capacity	A country is more likely to be environmentally sustainable to the extent that it has in place institutions and underlying social patterns of skills, attitudes, and networks that foster effective responses to environmental challenges.
Global Stewardship	A country is more likely to be environmentally sustainable if it cooperates with other countries to manage common environmental problems, and if it reduces negative transboundary environmental impacts on other countries to levels that cause no serious harm.

Table 9: 2005 Environmental Sustainability Index Building Blocks – Components

Box 1: "Sustainability" in the Broader Sense

The ESI does not track sustainability in the overarching "triple bottom line" (economicenvironmental-social) sense that is now often used. Sustainability in this broader sense is the dynamic condition of society that depends on more than the protection and management of environmental resources and stresses as measured with the ESI. It is also necessary to have economic sustainability, with wealth distributed so that extreme poverty is eliminated, capital accounts are in balance, and investments in wealth-generating assets are at least equivalent to their depreciation. In addition, no society can be considered sustainable without attention to the social dimension, including effective governance, social justice, and respect for diverse cultural, ethical, and spiritual needs. The ultimate sustainability of human society also depends on education, through which knowledge, science, culture, values and the accumulated experience that we call civilization are transmitted from one generation to the next. For a complete measure of sustainability, the ESI needs to be coupled with equivalent economic and social sustainability indices to give an integrated set of measures of the efforts of countries to move towards full sustainability. With such measures, it will be easier to explore and understand the interactions between the economic, social, and environmental dimensions of the human system.

Arthur Dahl International Environment Forum Geneva

DPSIR variant that additionally breaks out Driving Forces and Impacts¹. The cumulative picture created by these five components does not in any authoritative way define sustainability, but instead represents a comprehensive gauge of a country's present environmental quality and capacity to maintain or enhance conditions in the years ahead.

Indicators and Variables

While we separate the ESI into five components for analytic purposes, each of these components, in turn, encompasses between three and six "indicators" of environmental sustainability. We consider the 21 indicators to be the fundamental building blocks of environmental sustainability – and it is these 21 indicators that are aggregated to create the ESI.

Each indicator builds on a logic developed by a careful review of the science and the literature in the environmental field, as well as thorough consultation with many experts from across the environmental sciences, government, business, non-governmental groups, research centers, and the academic sector. Ideally, these indicators would include all relevant aspects of functioning environmental systems, be distinct in their cause-effect relationships, permit aggregation, reflect the diversity of circumstances across political jurisdictions (including disaggregated data for large countries), be easily quantifiable, and be scale-neutral.

Due to significant data gaps and conceptual limitations (such as how to measure and attribute the vitality of the oceans on a national basis), the actual indicator set falls short of the ideal. For example, a number of important issues including wetlands protection, the quality of solid and hazardous waste management, exposure to heavy metals and toxics, and ecosystem functionality were omitted because we lack adequate data to measure them across a significant number of countries. Other issues such as biodiversity loss, private sector contributions to sustainability, and progress towards more sustainable fisheries, forestry, and agricultural management practices are covered only to the extent available data permit. We discuss these data limitations and our vision of the "ideal" indicator set in Appendix G.

Figure 1: Constructing the ESI Score

The ESI score represents an equally weighted average of the 21 indicator scores. Each indicator builds on between 2 and 12 data sets for a total of 76 underlying variables. Air quality, for example, is a composite indicator that includes variables tracking the concentration of nitrogen oxides, sulfur dioxide, and particulates. Given the diversity of national priorities and circumstances, there will never be full agreement on a universally applicable set of weights for the aggregation of the 21 ESI indicators. Indeed, in some countries, water issues will be most pressing; in others, air pollution may be the priority. Developed countries are likely to put more emphasis on longer-term challenges such as climate change, waste treatment and disposal, clean and sustainable energy supply, and the protection of biodiversity. Developing nations will stress more urgent and short-term issues such as access to drinking water and sanitation, environmental health problems, and indoor air pollution.

We settled on uniform weighting of the 21 indicators because simple aggregation is transparent and easy to understand. Moreover, when we asked leading experts from the governmental, business, and non-governmental sectors to rank the indicators, none stood out as being of substantially higher or lower importance than the others. Similarly, when we tried to use statistical methods (including principal component analysis) to identify appropriate weights, nearly equal values were suggested across all 21 indicators. Thus, although on an individual country basis, different prioritizations are likely to exist, on average these differences in weighting are less pronounced. The details of this effort are discussed in Appendix A.

The sensitivity analysis in Chapter 4 furthermore shows that the choice of aggregation strategies (and the implicit weighting that results) does not matter for most countries. Aggregating at the level of the five components (which we do *not* do for the reason stated above) substantially changes the ranks for only a few countries - particularly those with high levels of pollution and high capacity as well as low environmental vulnerability. Belgium and South Korea, in particular, move up dramatically as their institutional strengths are given much more weight under component-based aggregation.

To improve the policy utility of the ESI and to respect the diversity of judgments about how to weight the indicators, we plan to introduce an interactive version of the ESI which will allow the user to adjust the indicator (or component) weights however he or she wishes, and then to calculate a new score.

By giving each variable within an indicator the same weight and weighting each of the 21 indicators equally, we provide an imperfect but clear starting point for analysis. Table 10 shows in summary the nesting of variables within indicators and indicators within components.

Comp- onent	Indicator Number	Indicator	Variable Number	Variable Code	Variable
			1	NO2	Urban population weighted NO ₂ concentration
		Air Quelitu	2	SO2	Urban population weighted SO ₂ concentration
	1	Air Quality	3	TSP	Urban population weighted TSP concentration
			4	INDOOR	Indoor air pollution from solid fuel use
			5	ECORISK	Percentage of country's territory in threatened ecoregions
			6	PRTBRD	Threatened bird species as percentage of known breeding bird species in each country
sm	2	Biodiversity	7	PRTMAM	Threatened mammal species as percentage of known mammal species in each country
Syste			8	PRTAMPH	Threatened amphibian species as percentage of known
ental S			9	NBI	amphibian species in each country National Biodiversity Index
Environmental Systems			10	ANTH10	Percentage of total land area (including inland waters) having very

	21	Environmental Pressures	76	POLEXP	Import of polluting goods and raw materials as percentage of total imports of goods and services

Data Coverage

We sought to include as many countries as we could in the 2005 ESI. For a detailed discussion of the inclusion criteria for countries, see Appendix A. Where countries were missing data points, we attempted to fill the gaps in a variety of ways. We sent out an initial data matrix to the Environment Ministry and the Statistical Office of every country that was close to meeting our data coverage threshold of 60% of the total variables, asking them to check our numbers and to fill gaps or update the data where possible. We accepted the data provided when they could be verified. A full discussion of this "country data review" is provided in Appendix A.

Ultimately, any country with fewer than 45 reported variables out of 76 was excluded from the analysis. We also excluded countries that did not meet baseline thresholds for land area and population because these small countries cannot be compared to others in the ESI. We discuss the complexity of including small countries and report the data for these countries in Appendix E.

A total of 146 countries met the criteria for inclusion in the 2005 ESI. For these countries, we then used Markov Chain Monte Carlo simulation to impute values for the missing variables where a logic for imputation existed.

Not only do data gaps mean that some important issues cannot be incorporated into the ESI, but many of the data sets that we do use are patchy, incomplete, haphazardly constructed, or otherwise deficient in some respect. In order to highlight where improved data is needed, we have undertaken to "grade" the 76 variables that are in the 2005 ESI on eight parameters. The results of this grading exercise are reported in Appendix A.

Data Transformation

To calculate the ESI scores for each country and to facilitate the aggregation of variables into indicators, the raw data were transformed in a variety of ways. A number of variables require appropriate "denominators" to permit comparisons across countries of different scales, including transformations to improve the imputation model and the symmetry of the data. To avoid having extreme data points skew the results, we "trim the tails" of each data set distribution and construct a "z-score" for each variable that preserves the relative position of each country for each variable while providing a neutral way to aggregate the variable into indicators. The details of this methodology are provided in Appendix A.

Comparing the ESI to Other Indicator Efforts

Despite the urgent need for indicators that allow tracking of environmental performance on a national basis, data on pollution control and natural resource management remain spotty at best. A number of UN agencies and other international bodies collect data, but much of the information is lacking harmonized methodologies, timeliness, and rigorous quality assurance and quality control protocols. Further investments in environmental data and the production of indicators must be made a point of focus for both national and global decisionmakers. Getting the appropriate analytic and empirical underpinnings for good decisionmaking is essential to successful policymaking.

In recent years, important indicator development work has been done on the local and regional scales by groups such as the International Institute for Sustainable Development, which produced the IISD Compendium of Global Indicator Initiatives (IISD 2004). Others have worked at the global scale, including the OECD, those working on the "Dashboard of Sustainability" (ESL 2004), and Robert Prescott Allen's work on the Wellbeing of Nations (Prescott-Allen 2001). However there are relatively few comprehensive environmental indicator sets that permit cross-national comparisons in support of sound policymaking.

For a variety of reasons, intergovernmental organizations have been unable or unwilling to produce such indicators, leaving an important void in the international policy realm. The closest the international community came in recent years was when the UN Commission on Sustainable Development adopted a work program on indicators that produced standard methodologies for extensive sets of indicators (UN CSD 1996; UN CSD 2001). The program aimed to help governments measure their own sustainability at the national level with sets of indicators they could adapt to their own requirements rather than a universal set of global indicators. But even here the CSD chose neither to endorse any single set of indicators nor to produce comparable crossnational indicators.

Although UN agencies and other international bodies routinely produce global indicators permitting cross-national comparisons on economics, health, security issues, human rights, and other high priority issues of global concern, efforts focused on the environment remain underfunded and understaffed. Instead, international agencies produce volumes of more broadly dispersed data on the environment. The information collected is often not methodologically consistent from country to country. This non-comparability hinders usefulness from a policy perspective.

In the absence of effective environmental sustainability indicators, it is impossible for environmental decisionmaking to undergo the virtuous circle of diagnosis, target-setting, implementation, and evaluation that is possible in other realms. Instead, environmental decisionmaking suffers from drift, with no clear expression of priorities, no coherent policy targets, and no ability to evaluate performance against objective criteria (Levy and Meier 2004).

Apart from the Ecological Footprint, when the ESI was first produced in 2000, there were no other cross-national environmental performance indices or rankings available. Since that time, a number of global-scale aggregate indicator efforts have emerged. We highlight below some of these other efforts and compare them to the ESI. A more technically complete discussion, including statistical comparisons, can be found in Appendix F.

Robert Prescott-Allen's Wellbeing of Nations (IUCN 2001) has much in common with the ESI. It combines measures of environmental and human wellbeing, using a series of thematic indicators, which are aggregated in an overall indicator of environmental wellbeing and human wellbeing, which in turn can be averaged to produce an overall indicator. It quantifies levels of sustainability in a broad range of environmental areas, including water, air. biodiversity. and landscape. The Wellbeing Index combines environmental outcomes with human outcomes and relies on relative rankings to generate aggregated quantitative indicators (although performance on individual indicators is measured against absolute benchmarks). Unlike the ESI, the Wellbeing of Nations does not include measures of social capacity and it is not updated. The Wellbeing Index has also been criticized for its lack of transparency in the determination of the underlying weighting scheme. While the ESI is also based on a weighted aggregation, its choice and justification of the weights is straightforward and transparent.

The Consultative Group on Sustainable Development Indicators (CGSDI) has produced a set of indicators spanning economic. environmental, and social development objectives, in a framework designed to be consistent with the UN Commission on Sustainable Development Indicator Initiative. The CGSDI collection covers a wider range of outcomes than the ESI, because its focus is sustainable development broadly defined, as opposed to environmental sustainability. It does not explicitly publish an aggregated overall index of sustainable development, although such an index is straightforward to calculate with the data produced. The CGSDI indicators, in spite of their explicit connection to the UN process, is weakly institutionalized, with no clear ongoing mechanism for data collection, evaluation, aggregation, analysis and dissemination.

The Ecological Footprint, developed by Mathis Wackernagel and his colleagues, measures the degree to which a given country is living within its ecological means. It aggregates the consumption of natural resources within a country in terms of the land area that is estimated to require the support of such consumption. This land area is then divided by the actual land area of the country - countries whose footprints are larger than their actual area are said to be consuming beyond a sustainable level. The Ecological Footprint has an intuitive appeal insofar as natural resource depletion is a central element of sustainability. It differs from the ESI in that it focuses on a single dynamic rather than a broader measure of environmental conditions. The ESI includes resource consumption and uses the Ecological Footprint as a variable because of its obvious relevance to sustainability. But the ESI also tracks many other aspects of environmental stewardship, particularly those associated with pollution and environmental public health.

Uncertainties and Conclusions

The validity, interpretability, and explanatory power of the Environmental Sustainability Index depend on the quality and completeness of the input data. Without sufficient data coverage at the national or sub-national scale, we would be unable to build the data matrix which underlies the Index, and we would have to rely more extensively on modeling techniques to fill the matrix gaps.

Data quality is also instrumental for the calculation of the indicators and Index. We are aware that there are many sources of uncertainty including measurement error, systematic and human error as well missing data. Despite our goal of minimizing these errors, the ESI must be understood as an emergent product, prone to some imprecision where these data difficulties persist.

We aimed for the highest possible quality of both the 2005 ESI data and the Index construction methodology by engaging in extensive peer- and country-reviews. The many responses received to our country "data review" requests are a testimony to the recognition of many environmental officials of the importance of accurate, current, and informative environmental data and indicators. Dozens of experts helped to update, refine, and critique the 2005 ESI. They contributed individually and collectively to ensuring that the 2005 ESI stands at the forefront of currently available environmental indices and indicator projects.

We recognize that several methodological issues, including issue/indicator selection and the equal weighting of our 21 indicators, are open to dispute. We have continuously reviewed and improved the ESI methodology – and we expect to continue to do so as more data become available and statistical techniques are refined. As noted above, our vision of what an ideal ESI ought to include – if the data were available – can be found in Appendix G.

Although the ESI as it stands is partial and constrained by data limitations, we see enormous value in having a comparative tool that helps to identify the leaders and laggards with regard to a broad range of environmental issues. It is in the spirit of providing a starting point for data-driven and empirically grounded policymaking that the Environmental Sustainability Index is put forward.

Box 2: Can Environmental Sustainability Be Measured?

Although we acknowledge that "measuring" environmental sustainability is challenging, there are some common misconceptions about how difficult it is. We address these misunderstandings below:

Argument: the concept is too abstract. It is true that environmental sustainability is an abstract concept, however it does not follow that it cannot be measured with concrete indicators. "Health" is an equally abstract concept, yet the World Health Organization has made great progress constructing useful cross-national indicators of aggregated health outcomes. "Poverty" is very abstract as well, but a number of useful indicators have been produced to permit target setting and evaluation. Many other examples can be cited in which abstractness is not an obstacle to measurement, for example, in the cases of corruption, democracy, or human rights. There is no reason to suspect that the environment is any different from other abstract concepts.

Argument: the concept is too multi-faceted. Some argue the measures proposed as constituents of environmental sustainability are causally connected in multiple ways, diminishing their ability to serve as indicators. It is true that the many indicators proposed in the ESI are connected through complicated pathways of causality. Levels of environmental pollution, for example, can diminish the state of environmental systems, and also affect people and organisms adversely, while social and institutional capacity can intervene either in directly altering any of these phenomena or in changing the nature of the causal connections among them. We agree that this reality makes indicator creation challenging. However, complex causal structures are not a reason for inaction; in fact, we argue that indicators can help make it possible to resolve disputes on causality by strengthening the empirical nature of policy debates.

Argument: the term "environment" covers too wide a range of issues. Environmental sustainability encompasses a wide range of issues from pollution to natural resource management challenges and institutional capacity. It requires attention to the past, the present, and the future. Underlying natural resource endowments and past pollution as well as resource consumption define the environmental starting point for any society. Current pollution flows and resource use clearly are important determinants of sustainability. And the ability to change trajectories – including the societal and institutional capacity to fix problems and improve results over time – is also a key driver of sustainability. In response, the issues reflected in the ESI *do* range widely. But this fact does not invalidate the ESI. To the contrary, the diversity of issues embedded in the concept of environmental sustainability makes the need for a broad-gauge ESI more clear.

Argument: there is no common unit of measurement. We agree that the availability of a common unit of measurement, in terms of monetary value, land area, population, or risk, would greatly facilitate the definition of environmental sustainability. However, the multi-dimensional framework of the ESI cannot readily be reduced to a common scale. Transforming the ESI's 21 indicators and underlying 76 variables to a common measurement metric would imply large-scale assumptions and generalizations that would bias the results and mask much of the analytic fraction of the index. Instead, making variables comparable on a cross-national level using GDP, people, or populated land area as denominators allows the aggregation of information that originally had different units of measurement and is the best option with the variety of the data included in the ESI.

Chapter 3 – Main Findings

ESI Scores and Ranks

The ESI ranking provides a relative gauge of environmental stewardship in 146 countries. The Nordic countries, Uruguay, and Canada occupy the top ranks and have consistently done so in previous ESI rankings (ESI 2001; ESI 2002). Other than Uruguay, these nations are highly developed countries endowed with natural resources, strong economies, and low population densities. As industrialized countries, they have substantial pollution stresses, but generally manage their environmental challenges well. Uruguay stands in the top tier for a slightly different reason. It is not very industrialized and thus faces relatively low environmental stresses. It does, however have some economic strengths and reasonably good political and social institutions and capacity. So while it does not score very high on any aspect of the ESI, it has no real weaknesses and thus lands in the top quintile across all the components.

At the bottom of the table, North Korea, Taiwan, Turkmenistan, Iraq, Uzbekistan, and Haiti are all countries with serious environmental stresses, poor policy responses, and (with the exception of Taiwan) limited institutional capacity. Among the next lowest five countries are both Kuwait and Saudi Arabia. Their presence at the bottom of the rankings, along with relatively rich Taiwan, suggests that a country's level of economic development does not exclusively determine its environmental performance. Most of the countries near the bottom of the rankings, however, suffer from the challenges of poverty and weak governance. It appears that poor environmental planning and limited investment in environmental protection and infrastructure as compared to the leading countries translate into markedly lower results (Esty, Levy et al. 2003).

While it is clearly possible to identify leaders and laggards and to pose hypotheses on the reasons for their positions at the high and low ends of the rankings, it is more difficult to analyze the middle ranks. In part, the volatility of the mid-ranking countries is a normal statistical result. Since the majority of countries have ESI scores located closely around the center of the ESI distribution, small movements result in larger changes in ranks compared to countries in the top and bottom positions.

Countries at various stages of economic development, human development status, and geographical size and location have ESI values in the mid-range of 40 to 60. This fact seems to indicate that environmental sustainability challenges come in multiple forms and combinations. The diversity of underlying institutions – including economic systems, legal regimes, and regulatory systems – adds to the complexity of the picture.

While definitive statements are hard to make using the existing data, it does not appear that any country has yet achieved sustainability. Nevertheless, the ESI can be useful in the search for role models and best practices. Lagging countries might look to the leaders, as shown in the relevant peer group charts, and adopt the policy instruments, technologies, and approaches of these leading-edge nations. Because the ESI is an aggregate index, the search for policy models is best conducted at the indicator or variable level rather than at the level of components or total ESI score. For example, if the United States wanted to improve its environmental performance (and its ESI score), it should focus on its lagging indicators, such as its high levels of waste and greenhouse gas emissions.

Note: The 2005 ESI scores are not directly comparable to the 2002 ESI Scores. See Appendix A for details on the methodology.

Box 3: How to Interpret an ESI Score

The ESI score quantifies the likelihood that a country will be able to preserve valuable environmental resources effectively over the period of several decades. Put another way, it evaluates a country's potential to avoid major environmental deterioration. The top-ranked country, Finland, has high scores across all the ESI's five components. Because it is doing relatively well across such a broad range of environmental sustainability dynamics, we expect it to be more likely to provide its citizens with high levels of environmental quality and services into the foreseeable future. The bottom-ranked country, North Korea, scores low in many dimensions, but not in all. It is the weak performance in a large number of indicators that generates the low overall score, which supports a conclusion that North Korea's medium-term environmental prospects are not good.

Because the different dimensions of environmental sustainability do not always correlate with one another, the ESI score taken by itself does not identify the relative contribution of the different indicators to the overall assessment of a country's medium-term prospects, nor what particular types of challenges are most likely to pose acute problems. Although North Korea has the lowest ESI score, for example, its Environmental Stress score is closer to the world median. The United States, by contrast, has a far higher ESI score (45th) than North Korea, but has a worse Environmental Stress score. Therefore, although we would conclude that the United States is more likely to be able to preserve its valuable environmental resources effectively than North Korea, it is probably more likely to encounter problems that stem from high levels of pollution or high rates of conversion of natural land. In some areas the U.S. has extremely poor scores (greenhouse gas emissions are a notable example). However, these are balanced by above average scores in many others areas, especially preservation of wilderness and investment in capacity.

Gabon is the highest-ranked country in Africa, which means that our analysis concludes that it is the African country least likely to experience major environmental deterioration in the short and medium-term future. It does not mean that Gabon is without problems. Contributing significantly to its high ESI score are its very high ranks on a number of natural resource measures, which account for it having the third highest overall score for environmental systems. As a developing country it has below-average scores on capacity, and this fact is likely to pose significant challenges to the country as it faces the future. Its ability to move forward effectively, though, is enhanced by its relatively good scores on human vulnerability and global stewardship.

Several countries in Latin America are in the top 20, including Uruguay which is ranked 3rd overall. This outcome reflects a few facets of these countries' development paths. Although some South American countries have acquired negative reputations for abuses of natural resources, such as the rapid Amazonian deforestation in the 1980s, for the most part the region remains rich in wilderness and managed natural resources. In some cases, policy innovation has contributed to dramatic improvements in controlling resource losses, such as the programs to combat illegal logging in Brazil. In addition, many of these countries have a large share of their economies devoted to agriculture, as opposed to heavy industry, which shifts the pollution to non-point sources for which data sources are not readily available. Their prominence in the top-20 list of ESI scores is also a function of the fact that they are more wealthy than most of Africa, and therefore can invest in significant capacity and vulnerability reduction; that they are less industrialized than North America, Europe, and much of Asia; and that they have retained greater wilderness than most world regions. While these facts do not guarantee that these countries will avoid environmental problems, they do suggest that their overall likelihood of major problems is lower than elsewhere.

Developed v. Developing Country Environmental Sustainability

While environmental sustainability is complex and hard to define, the ESI suggests that sustainability has multiple dimensions - and distinct challenges for developed versus Developed countries developing countries. must find ways to manage the environmental stresses of industrialization and consumption of natural resources, particularly those that are non-renewable. Developing countries face the risk of depleting renewable resources such as water and forests as well as the challenges of funding investments in environmental protection and creating functioning institutions that permit economic growth and support appropriate regulation.

While the core environmental challenges vary across countries, the ESI facilitates the process of finding relevant peer groups and benchmarking performance. Because of the range and complexity of issues that fall under the environmental rubric, policymaking needs to be made more data-driven and empirical. The ESI supports this goal.

As in previous ESI rankings, no country (except Uruguay) scored in the top quintile in all five components. This fact suggests that countries tend to experience sustainability as a multidimensional challenge where each country has strengths and weaknesses and a unique profile (see Appendix B for the complete set of country profiles). Every country thus has something to learn from its peers and multiple areas for environmental improvement.

Relationship to Economic Development

Economic conditions affect environmental outcomes, but a country's level of development is by no means the only driver of its performance and ESI score. Richer countries tend to score high in human vulnerability and social and institutional capacity, and poorer countries tend to score higher in reducing environmental stresses and environmental systems. The global stewardship component has no clear relationship to income.

An individual country's performance is, therefore, best understood by looking not only at its overall ESI score or ranking but by examining its results with respect to the 21 key indicators of environmental sustainability. Because the 21 indicators span many distinct dimensions of environmental sustainability, it is possible for countries to have similar ESI scores but very different environmental profiles. The component-based bar chart in Table 1 highlights in summary form these differences. The "cluster analysis" discussed below further illuminates the range of sustainability challenges. Take, for example, the difference between Spain and Indonesia in Figure 2.

The analysis of the relative performance of countries with similar ESI scores but different indicators profiles helps to illuminate the range that exists across the most pressing environmental challenges countries face. The analysis of the differences and similarities among countries within the same peer group offers insights into the relative efficacy of their environmental policies – such as air pollution controls, biodiversity initiatives, and innovation in science and technology.

Spain, with an ESI score of 48.8 must deal with burdened ecological systems and quite high levels of environmental stress, as the "spider" graph on the next page suggests. Like other developed countries, Spain has reasonably strong capacity to handle the harms it faces. Indonesia, on the other hand, has a similar ESI score of 48.8, but faces a very different set of challenges. It has stronger underlying systems and less present stress in several regards, but much less developed institutional capacity to manage the challenges it must address, including severe water quality issues.

Figure 2: Comparison of Indicator Scores for Spain and Indonesia Note: the greater the distance from the center, the better the indicator result

At every level of development, there exists a large range of ESI scores. This fact suggests that countries in similar circumstances have available a variety of environmental management strategies, some of which are much more effective than others. Whatever a country's development status, the ESI offers a useful tool for isolating appropriate policy interventions and environmental approaches.

Relationship between Environmental & Economic Performance

Traditional economic theory posits a tradeoff between economic progress and environmental

quality. More recently, it has been suggested that increased wealth is a prerequisite for environmental improvements (Grossman and Krueger 1995). Several empirical studies have likewise shown that wealth is an important factor in explaining environmental policy results, but not alone determinative of environmental policy (Esty and Porter 2005). The low rankings of Kuwait, Saudi Arabia, and the United Arab Emirates suggest that there is no necessary connection between income and environmental success. Similarly, some developing countries, such as Costa Rica, place significant emphasis on the protection of their environmental assets. They have, as a result, environmental outcomes that are far better than would be predicted by their level of development.

Figure 3: Regression of 2005 ESI on GDP (PPP) Per Capita

ESI versus Per Capita Gross Domestic Product (GDP)

In statistical terms, about 23% of the variance in the ESI is accounted for by per capita GDP. This result suggests that richer countries can – and do – invest in pollution control and other environmental amenities. Examining Figure 3 above, which provides the regression results of the ESI on GDP per capita, helps to illuminate the relationship between wealth and environmental results.

As indicated by their position above the regression line, the Nordic countries have high GDP per capita but even higher ESI scores than their wealth might forecast. The United Kingdom, Belgium, and the United States fall well below the regression line – indicating

sub-par performance given their level of wealth.

Likewise, Trinidad and Tobago falls below Argentina and Brazil among medium-income level countries. And Tajikistan and Uzbekistan lag behind Guyana among low-income countries.

If we examine the ESI's components, we can get a more precise picture of the relationship to per capita income. The highest positive correlations are between GDP per capita and the ESI's Human Vulnerability and Social and Institutional Capacity Components. The correlation is negative for environmental stresses, meaning that high-income countries put significantly more stress on their environments than low-income ones.

Figure 4: Regression of 2005 ESI on 2004-2005 Growth Competitiveness Index

ESI versus Growth Competitiveness Index

Classic economic theory suggests that a commitment to high levels of environmental performance might well negatively affect competitiveness. Michael Porter (Porter 1991) and others (Porter and C. van der Linde 1995) have suggested, however, that this presumption might be wrong under dynamic conditions. Regressing the ESI on the World Economic Forum's Growth Competitiveness Index scores provides a starting point for testing these competing hypotheses.

The Competitiveness Index explains approximately 19% of the variation in the ESI. As Figure 4 shows, competitiveness correlates positively with environmental sustainability. We cannot say whether this correlation implies any statistically significant causal relationship. The cautious conclusion is that a commitment to sustainability is compatible with national economic competitiveness. As with wealth, countries with the same Growth Competitiveness Index (GCI) value often perform very differently in the environmental sphere. These results suggest that some countries handle environmental challenges without seeming to harm their competitiveness.

Finland and the United States have similar GCI scores, but Finland has a much higher ESI score. Similarly, Sweden, Iceland, and Norway are well above the regression line, while China, Trinidad and Tobago, and South Korea fall far below the line. To better understand these relationships, it may be useful to look at the correlations not just with the ESI as a whole but with the core components and underlying indicators. Table 12 below provides, in summary form, the most significant relationships. These results suggest that economic strength is a critical factor in addressing environmental challenges.

		2004 GCI	Significance	GDP/cap	Significance

Central Role of Governance

In recent years, a growing emphasis has been placed on "governance" as a critical underpinning of policy success generally and environmental progress more specifically. The ESI provides some support for the focus on governance. In fact, if one looks at the correlations between the ESI and the 76 underlying variables, the strongest bivariate correlations all include elements related to governance as Table 13 on the next page shows.

The highest bivariate correlation is with civil and political liberties, suggesting that countries where robust political debate takes place - facilitated by fair elections, free speech, engaged press, active NGOs, vibrant legislatures, etc. - are more likely to focus on environ-The second highest mental challenges. correlation is with survey data on environmental governance. This result suggests that countries that pay attention to environmental policy and regulate effectively are more likely to produce successful environmental outcomes. The third, fourth, and fifth highest correlations are similar variables, including World Bank gauges of governmental effectiveness and rule of law as well as a University of Marvland measure of the democratic character of political institutions.

Variable Code	Variable with Statistically Significant Correlation with ESI	Correlation Coeficient	Significance
CIVLIB	Civil and Political Liberties	0.59	***
WEFGOV	World Economic Forum Survey on environmental governance	0.54	***
GOVEFF	Government effectiveness	0.51	***
POLITY	Democratic institutions	0.50	***
LAW	Rule of law	0.50	***
PARTICIP	Participation in international environmental agreements	0.49	***

Table 13: Variables with Statistically Significant Correlation to the ESI

*** statistically significant at <0.01 level

The variable tracking participation in international environmental agreements is the sixth most highly correlated with the ESI, suggesting a relationship between engagement in global governance and environmental policy success. While none of these correlations necessarily imply a causal connection, the coincidence of strong governance with high ESI scores is striking.

Finding Peer Countries – Cluster Analysis

As noted earlier, one of the most valuable uses of the ESI is as a mechanism for comparative policy analysis. In the quest for improved performance, it is very helpful to identify appropriate peer countries against whom one can benchmark environmental outcomes and policies. In addition, those at the leading edge of the peer group might also be looked to for best practices in the policy or technology domains.

Not only do peer countries provide a relevant context for judging one's own performance and perhaps a source of policy guidance, but the compilation of rankings within a peer group also spurs competition. One of the most powerful lessons of the earlier versions of the ESI is that national political leaders care a great deal about how their countries stack up against those who they consider to be similarly situated. When the Norwegian prime minister met with the ESI team, he was not satisfied with Norway's second place rank in the 2002 ESI. Instead, he wanted to discuss was what his country would need to do to overtake Finland for first place.

As noted in Chapter 1, one way to identify peer countries is through existing political institutions such as the European Union or ASEAN. But another way to identify relevant points of comparison is through statistical We therefore conducted a cluster means. analysis, which identifies statistically related groups of countries based on the similarity of indicator scores. While we can force the statistical tools to generate any number of clusters, we find that the seven groupings identified in Table 14 on the next page represent a particularly interesting set of peer We see these clusters as having groups. observable similarities and thus representing a useful point of departure for policy comparisons.

The fact that the clusters include many geographically connected countries, suggesting that they have similar underlying environmental characteristics, provides a logic for regional benchmarking.

Table 15: Characteristics of Clusters

* Note: Higher z-scores correspond to more effective environmental governance.

Cluster 1 represents relatively high population density industrialized countries with above average social and institutional capacity. Cluster 2 groups the least-developed countries, most of whom experience relatively low environmental stress, but have very weak institutional capacity and are particular vulnerable to natural disasters, undernourishment, and lack of sanitation and safe water supply.

Distinct from the first set of developed countries, Cluster 3 is formed by large land area, low population density countries with low levels of vulnerability and well-developed institutional capacity. Cluster 4 encompasses many of the countries of the former Eastern Bloc along with a handful of other nations (Jamaica, Lebanon, Trinidad & Tobago, and Turkey) who have similar patterns of moderate systems and environmental stresses and relatively low human vulnerability.

Cluster 5 brings together a large number of Central and South American countries, along with a few African countries, which all show relatively strong environmental systems, and middle-tier results with regard to their vulnerability and capacity. Cluster 6 includes Russia and the most ecologically burdened of the former republics of the Soviet Union along with a number of Middle Eastern countries (and a few other nations) who have average environmental systems, stresses, and human vulnerability but very low capacity and global stewardship. Cluster 7 covers largely high population density, middle-tier developing countries with strained ecological systems but middle-range scores across the rest of the components.

ESI in Action

Because the ESI was the first effort to rank countries according to their environmental sustainability, it generated considerable attention. Approximately 100,000 downloads of the 2002 ESI report were recorded at Columbia University servers, and the report was made available through other websites as well. The ESI website has been widely read and linked from many locations. It is the second site listed in a Google search for the phrase "environmental sustainability." This attention itself illustrates the desire for information and quantitative metrics of environmental sustainability.

In the course of the five years since the release

of the pilot ESI, many countries have used the ESI as a policy guide. Their experiences provide a powerful logic for further efforts to refine the ESI and other environmental indicator efforts. We highlight some of these experiences below.

Mexico's low ranking in the pilot 2000 ESI sparked a cabinet-level review within the country ordered by President Ernesto Zedillo who had read an account of the ESI in *The Economist.* An exchange of visits took place between the ESI team and Mexico's environment and natural resources ministry, SEMARNAT, in order to explain the ESI methodology and data sources and to demonstrate how the ESI's measures related to

Box 4: The Environmental Sustainability Index in the Philippines

The Environmental Sustainability Index as a basic conceptual and analytical framework has now been introduced to the discourse on environmental policymaking in the Philippines. As Member of the Committee on Appropriations and Vice-Chair of the Committee on Ecology, I learned of the ESI and argued for its inclusion as a framework for discussion in budget hearings for Department of Environment and Natural Resources (DENR) and its enforcement arm, the Environmental Managment Bureau (EMB). Noting the consistently dismal ranking (the lowest among the countries in Southeast Asia) of the Philippines, I insisted again on the government using the ESI as a policy tool in budget hearings in subsequent years.

In advancing the Philippines Clean Air Act, I proposed that the ESI and its measurement criteria be utilized as a benchmark for the assessment and evaluation of environmental policies and sustainability in our country. In a span of four years, two Secretaries of the DENR took careful heed of such proposals and instructed mid-level DENR directors to view and adopt the ESI – in whole or in parts – as a helpful, albeit tentative, gauge of the department's performance. While the DENR has stopped short of formally institutionalizing the ESI, the focus on quantitative measurement of performance has become integral to the decisionmaking and evaluation processes within the department.

As the new Chair of the Committee on Ecology in the House of Representatives, I have renewed the call for government to be more serious about measuring the efficacy of programs and policies on a range of environmental issues and sectors. With the dearth of data-driven environmental indices in the country, the ESI could well provide a reasonably sound basis for judging which technologies, approaches, strategies and regulatory mechanisms are effective or in need of improvement or overhaul. I am confident that the Philippine government will see fit to move towards more empirically based policy-formulation – notably in the environmental realm, with the ESI as an example.

Neric Acosta Congressman, Philippine House of Representatives Chair, Committee on Ecology (2004 - present) Manila environmental activities within Mexico. One of the most immediate consequences of this review was a high-level delegation from Mexico that visited the World Bank and the World Resources Institute to explore more effective ways to have their publications reflect recent Mexican data.

After Vicente Fox's election as President of Mexico in 2000, Mexican interest in the ESI intensified. Victor Lichtinger, Fox's first Environment Minister, put in place a set of policy reforms that prominently featured quantitative environmental sustainability metrics. In addition, reforms were adopted providing for enhanced transparency concerning environmental information.

Mexico has failed to fully implement Lichtinger's metrics-based sustainable development strategy. Nonetheless, the environmental policy agenda within Mexico has been permanently altered. Sustainability indicators now receive much more attention, and this sensitivity is seen within the private sector as well as the government. The Mexican Business Council on Sustainable Development released state-level а set of sustainability indicators in 2001.

South Korea embarked on a similar set of internal evaluations stemming from its 8th from bottom ranking in the 2002 ESI. The Ministry of Environment carried out a study examining the factors accounting for the low rank, and invited a representative from the ESI team to visit the country to meet with members of government, industry, civil society, and academia. The country sent two environmental policy experts from the Korea Environment Institute to spend a month with the ESI team learning the ESI methodology. The government adopted a strategic plan aimed at improving its rankings in a number of high-profile global indices, including the ESI. Special attention was paid to water policy and to patterns of international collaboration.

The United Arab Emirates, ranked second from the bottom in the 2002 ESI, launched a major internal review to explore the reasons for its low position and brought two members

of the ESI team to the country for a series of high-level meetings. The most concrete response came from the Emirate of Abu Dhabi, which launched a regional initiative to dramatically improve the ability to monitor and communicate environmental conditions. This initiative, formally launched at the 2002 World Summit on Sustainable Development, is now being implemented.

Belgium ranked far below other European countries in the 2002 ESI, which triggered substantial media attention and political inquiry, including parliamentary hearings. The environmental authorities, particularly those in the Walloon region, undertook an issue-by-issue review of the ESI. This effort helped to identify a number of problems related to the gathering and reporting of environmental data, as well as raising a number of important theoretical questions about the construction of the ESI. The Walloon authorities recalculated the ESI based on updated data for Belgium but found that their nation still lagged other EU countries. This result spurred a focus on various policy shortcomings in Belgium, including the division of responsibilities among Belgian, Flemish, and Walloon authorities.

The Global Environmental Monitoring System Water Program (GEMS Water) has been an important source of data for the ESI because it is the primary source of comparable international information on surface water quality. The ESI reports were straightforward in their assessment that the suitability of the GEMS Water data for comparing water quality across nations was very low. In the past, very few countries provided data to the program and the data were difficult to obtain. When the 2003 World Water Development Report reprinted the 2002 ESI water quality indicator data, it drew attention to water quality data issues. Some governments were unhappy with the fact that the data table included only estimates of water quality where data was missing from GEMS Water. Others were dissatisfied with the fact that some countries reported data from a large number of water monitoring stations whereas others reported only a small number.

These complaints drew high-level attention to the serious deficiencies in the GEMS Water program, and played a significant role in a strategic effort to build the program into a more robust repository of relevant water quality data. A major drive was launched to bring new countries into the program. The approach shifted from passively receiving data from countries to actively requesting data updates on a regular basis. In addition, the data was made much more easily accessible. As a result of these changes, participation in GEMS Water has grown from less than 40 countries when the ESI first started using the data to over 100 countries today, although data coverage is still low. While the ESI cannot take credit for this shift, it did contribute to it by aggregating the GEMS Water data into national indicators and raising those indicators to high prominence.

Scholarly studies have made use of the ESI data to facilitate quantitative exploration of environmental phenomena. A partial list of known citations is provided in Appendix I. Globerman and Shapiro (2002), for example, modeled foreign direct investment flows as a function of governance structures and of environmental and development outcomes, and utilized the ESI effectively as a proxy for environmental outcomes. Several studies have sought to compare the ESI to alternative sustainability measures (Parris and Kates 2003), or as a benchmark by which to evaluate new indicators (Sutton 2003).

Some studies have made use of components of the ESI in order to construct new indicators for other purposes (Birdsall and Clemens 2003). The ESI has also been used for pedagogical purposes allowing educators to create quantitively-based themes related to environmental stewardship.

Limitations

The results of the 2005 ESI should be seen as a relative gauge of environmental performance and a tool for highlighting policy issues that need to be addressed. The resulting rankings are subject to a number of uncertainties and qualifications. Our knowledge of environmental sustainability is incomplete, and our ability to draw precise conclusions is hampered by additional elements of uncertainty such as measurement error and missing data.

We do not have sufficient information to estimate the uncertainty due to knowledge gaps and measurement problems, but we can estimate the degree of error due to missing data. Although it underestimates the true uncertainty associated with the ESI scores, in Appendix A we report the variability in the ESI scores and ranks due to different sources of uncertainty and modeling assumptions as a measure of the level of confidence that can be placed on the ESI. 2005 Environmental Sustainability Index Report

This page is intentionally blank.

Chapter 4 – Sensitivity Analysis

The robustness of the ESI cannot be fully assessed without evaluation of its sensitivity to the structure and aggregation methods utilized. To test this sensitivity, the ESI team launched a partnership with the Joint Research Centre (JRC) of the European Commission in Ispra, Italy. A short version of their findings is below. The more detailed version is included in Appendix A.

2005 ESI Sensitivity Analysis

Prepared by Michaela Saisana, Michela Nardo, and Andrea Saltelli (Applied Statistics Group), Joint Research Centre of the European Commission

Every composite index, including the ESI, involves subjective judgments such as: the selection of variables, the treatment of missing values, the choice of aggregation model, and the weights of the indicators. These subjective choices create the analytic framework and influence the message it communicates. Because such indices can send non-robust policy messages if they are poorly constructed or misinterpreted, it is important that their sensitivity be adequately tested.

Because the quality of a model depends on the soundness of its assumptions, good modeling practice requires evaluating confidence in the model and assessing the uncertainties associated with the modeling process. Sensitivity analysis lets one see the impact of the model frame by studying the relationship between information flowing in and out of the model (Saltelli, Chan et al. 2000).

Using sensitivity analysis, we can study how variations in ESI ranks derive from different sources of variation in the assumptions. Sensitivity analysis also demonstrates how each indicator depends upon the information that composes it. It is thus closely related to uncertainty analysis, which aims to quantify the overall uncertainty in a country's ranking as a result of the uncertainties in the model. A combination of uncertainty and sensitivity analyses can help to gauge the robustness of the ESI ranking, to increase the ESI's transparency, to identify the countries that improve or decline under certain assumptions, and to help frame the debate around the use of the Index.

The uncertainty and sensitivity analysis explores the effect of four main uncertainties/ assumptions in the ESI: (1) variability in the imputation of missing data (2) equal v. expert weighting of indicators (3) aggregation at the indicator v. the component level, and (4) linear v. non-compensatory aggregation schemes.

The main findings are summarized below. The detailed methodological approach and results are given in Appendix A.

Overall, the ESI shows only modest sensitivity to the choice of aggregation, indicator weighting, and the imputation procedure. For most countries, the possible scores and ranks are rarely at odds with their actual ESI score when tested against various combinations of assumptions in the sensitivity analysis. For 90 out of 146 countries, the difference between the ESI rank and the most likely (median) rank is less than 10 positions, given that all sources of uncertainty are simulated simultaneously. This outcome implies a reasonable degree of robustness of the ESI.

Which countries have the most volatile ranks and why? The top ten ranking countries in the ESI all have modest volatility (2 to 4 positions in the ranking) with the exceptions of Guyana (23 positions) and Argentina (9 positions). This small degree of sensitivity implies a very limited degree of uncertainty about the ESI scores for these countries. Guyana's high volatility can mainly be attributed to imputation uncertainties (28 variables out of 76 have been imputed) as well as the choice of the aggregation level. Argentina's volatility is entirely due to imputation, although only 5 variables have been imputed. The countries with the highest volatility (50 to 80 positions) are found between rank 39 (Congo) and rank 113 (Dem. Rep. Congo), which is partially due to the conversion of tightly bundled ESI scores to equidistant ranks.

Would the ESI be more stable and useful if no imputation had been carried out? Imputation allows us to include many countries in the ESI that would otherwise have to be dropped for lack of data – and it reduces the incentive for a country to fail to report data in categories where its performance is weak. Imputation, however, reduces to some degree our confidence in the accuracy of the scores and rankings. Imputation affects countries with larger amounts of missing data more than others. But this relationship is not entirely straightforward. Among the countries that are missing almost 33% of the observations, only Guinea-Bissau and Myanmar are highly susceptible to rank changes due to imputation. If no imputation had been applied, Syria, Algeria, Belgium and Dominican Republic would have improved by between 9 and 37 positions. Conversely, Mali, Guinea-Bissau, Myanmar and Zambia, would go down 27 to 43 positions. Overall, imputation creates an average uncertainty of 10 ranks.

What if a "non-compensatory" aggregation scheme had been used, instead of the linear aggregation scheme? Aggregation schemes matter mainly for the mid-performing countries. When the assumption of compensability among indicators is removed, countries having very poor performance in some indicators, such as Indonesia or Armenia, decline in rank, whereas countries with fewer extreme values, such as Azerbaijan or Spain, improve their position. Overall, the aggregation scheme methodology has an average impact of 8 ranks.

What if aggregation had been applied at the component level instead at the indicator level? Weighting the 5 components equally versus weighting the 21 indicators equally has only a small effect on most countries. But a few are significantly affected. For example, Belgium and South Korea improve their rank by almost 40 positions if aggregation is done at the component level. However, countries such as Congo or Nicaragua decline by 30 positions. This movement is can be traced to the fact that aggregation at the component level gives added weight to the components with fewer indicators (e.g., Reducing Human Vulnerability and Global Stewardship). Overall, the assumption on the aggregation level has an average impact of 8 ranks, similar to the impact of the aggregation scheme.

What if a set of expert-derived weights had been used for the 21 indicators instead of the equal weighting? An alternate weighting obtained by surveying the experts at the December 2004 ESI Review Meeting assigns slightly higher values to indicators within the System and Stress Components of ESI and less to the remaining indicators. Using these weights has a pronounced positive effect on the rank of a few countries such as Sri Lanka and Niger, but a negative effect on others such as the Chile, South Africa or Italy. Overall, the analysis shows only a small sensitivity to the weighting assumption with an average impact of 5 ranks.

Chapter 5 - Conclusions and Next Steps

The ESI is fundamentally a policy tool designed to make environmental decisionmaking more empirical and analytically rigorous. It provides a way to benchmark performance, highlight leaders and laggards on an issue-byissue basis, and facilitate efforts to identify best practices. In these regards, the ESI represents an important step forward. But the data on which the ESI builds are crude and patchy, and the methodologies for combining data sets into a single index continue to be refined.

Measuring trends with respect to environmental sustainability is a conceptually difficult and ambitious undertaking. We recognize the many layers of uncertainty surrounding the measurement of environmental sustainability: the lack of a clear definition of the concept and benchmarks against which to verify current performance; the need to fold into a common metric the past, the present, and the future; the implicit assumptions and judgments made in the selection of the variables and indicators as well as their aggregation, and the uncertainty resulting from data gaps, including the possibility of failing to measure important aspects of environmental sustainability.

Yet, local, regional, and global environmental problems are increasing at a rate and scope that demands new approaches to facilitate action. As a "process," the ESI is designed and made available to the public in a transparent wav. Its imperfections are openly acknowledged and discussed. Its use as a sustainability measure is largely constrained to serving as a tool for policymakers to signal trends in environmental pollution, natural resource use, environmental health, social and economic factors as well as international environmental law and policy. Although the ESI score provides a snapshot view of the relative position of countries, more informative analysis derives from the 21 indicators and underlying data sets. Simply put, no country will achieve sustainability by tracking the ESI score alone. Identifying the areas for improvement using the ESI's stepwise hierarchy offers a more fruitful approach to policy progress.

The problem of persistent data gaps, slow adoption of remote sensing and GIS technology for environmental monitoring, and incompatible methodologies constitute the most serious impediment to giving a full and unbiased picture of environmental sustainability trends. The quantitative basis is stronger in OECD countries than in many low-income nations especially in Africa and Asia. Consequently more data need to be imputed to calculate the indicator, component, and ESI values in these countries. The gaps and our imperfect means of filling them increase the uncertainty associated with the results.

Despite the data gaps, the statistical foundation of the 2005 ESI represents a significant refinement from earlier editions of the ESI. We made more extensive use of statistical modeling and analysis techniques to (i) impute missing data (ii) investigate similarities and differences among the countries with respect to their environmental performance and socioeconomic driving forces (iii) understand better the relationships between the variables and indicators in the ESI, and (iv) rigorously test the sensitivity of the ESI to the implicit and explicit assumptions and methodological choices made. The results have facilitated several improvements to the ESI's construction as well as its interpretation.

The variables included in the ESI have also been updated with new data sets, more recent information, and extended geographical coverage by merging different data sources where possible and by developing new variables based either on new data initiatives or our own design. The country review of the ESI data has provided updated data and useful feedback, which have improved the ESI substantially.

Although we cannot determine with any satisfactory level of accuracy the precise position of a country on an overall basis, we can identify clearly the leaders and the laggards. Seen in this context, the ESI has proven to be a useful gauge of national environmental stewardship, providing a valuable counterpart and counterpoint to GDP growth as a metric of governmental policy "success."

We cannot say with confidence that any country is currently on a sustainable trajectory. Indeed, we do not have established benchmarks against which to measure long-term sustainability. But the variables and indicators in the ESI shed light on a range of unsustainable pollution and consumption paths. Every country faces serious pollution problems and is experiencing unsustainable levels of consumption of some natural resources. There are, however, significant differences in the progress toward sustainability within different societies. By assembling a broad array of data and metrics on a basis that makes crosscountry comparisons possible, the ESI provides a powerful benchmarking tool and a valuable mechanism for identifying leading performers on each issue and isolating the best practices which they follow.

The ESI also helps to highlight some of the critical factors that shape environmental performance including: the quality of governance, the lack of corruption, and low population density. Some of these variables have long been identified as theoretically important. The ESI provides empirical support for these theories.

While environmental sustainability has become a buzzword, the concept of sustainability – with its combination of past, present, and future timeframes – inescapably presents some serious methodological complexities. The concept is dynamic and requires constant monitoring and re-adjustment. On the country level, sustainability is affected strongly by natural resource endowments, past development paths, current and future pressures, and capacities to deal with them. To provide policymakers with more immediate feedback on their current policy performance, a more focused index and set of indicators will be needed. With this goal in mind, the ESI team plans to develop an environmental policy barometer that gauges more narrowly the impacts of current environmental policies, including pollution control, natural resource use and management, and environmental health regulations, on environmental outcomes such as air and water quality, land and habitat protection, exposure to environmental toxins, and the provision of global public goods. The project aims at supporting the Millennium Development Goals, specifically Goal 7 "Ensuring Environmental Sustainability." The new initiative will center on a system of target-oriented indices that track performance of countries towards the established policy goals.

Future Directions

While the ESI represents the state of the art in performance measures of environmental sustainability, it has limitations as a policymaking guide. We see a number of directions for future work, both technical and institutional.

All indices are handicapped by the poor quality and coverage of available data, with inconsistent methodologies, poor time series, and significant gaps, particularly for developing countries. There is no simple centralized solution to this problem. It requires a longterm effort by many partners. Each individual data set for a variable should be the responsibility of an appropriate organization that can ensure its quality control and regular updating. Governments need to recognize their primary responsibility for data collection. Public investments in data collection are more than repaid in improved decisionmaking. International assistance needs to be provided to countries without the capacity or resources to collect all the data necessary. Better coordination is needed among the providers of data sets

This effort should be extended to build new data sets for key variables and indicators that should be in the ESI but had to be omitted for lack of adequate data. There is a particular gap in measures of sustainable resource management in productive activities, such as agriculture, forestry, and fisheries. New technologies such as remote sensing and automated monitoring stations are making it possible to produce new uniform global data series for various environmental parameters. In this regard, we believe that collaboration among the new Global Earth Observation System of Systems (GEOSS), the Integrated Global Observing Strategy (IGOS) Partnership and the various global observing projects to define and generate new data sets will better capture aspects of environmental sustainability, such as land use and vegetation changes, soil degradation, salinization, and air and water pollution.

Filling the gaps in the ESI will both help to move towards an ideal ESI, which would include all critical environmental parameters, and improve the balance and weighting of variables and indicators within the ESI. We are also committed to engaging with others who may be in a position to help eliminate data gaps.

Data availability has limited the ESI to "snapshot" measures at a single point in time, yet sustainability has much to do with dynamic changes and trends over time. We will work to develop the variables as time series data that can give the direction and speed of change, and thus the distance to sustainability targets. For some variables, this target will be reducing a damaging activity or pollutant to minimal levels; for others, sustainability will mean striking a balance between two undesirable extremes, and each variable should be scaled accordingly.

The ESI is not yet mature enough to begin comparing ESI values between editions. There are too many refinements in the methodology and improvements in variables for such comparisons at present. This flux will probably continue for some years. However, it is possible to back-calculate the ESI for previous years using the latest methodology and variables, in order to begin measuring not only the relative performance between countries but also how each country's performance is changing over time. Finally, the production of the index itself needs to be put on a sustainable basis through better institutionalization. While it is quite appropriate that innovative measures like the ESI should be developed in an academic setting, an operational index for regular use by governments will be more credible if it becomes the responsibility of an appropriate international organization.

We hope to build the interest of governments in the ESI, and with their support discuss with intergovernmental bodies such as UNDP, UNEP, and the UN Statistics Division where an operational ESI might best be situated. Support for the ESI, and the development of various derivative products, could also be explored with other global and regional intergovernmental bodies and specialized agencies. Non-governmental organizations such as the World Resources Institute and Redefining Progress (with its Ecological Footprint) should also be involved, as should the private sector through organizations such as the World Economic Forum.

To build the case for the continued financing of the production of the ESI, and the generation of the necessary data series, some attention should be given to cost-benefit analyses of more data-driven decisionmaking. One of the goals of the ESI is to show the advantages of better science-based information. Some case studies of its impact on government decisionmaking processes and the resulting benefits would facilitate the transition of the ESI from an academic research program to an operational tool for decisionmaking.

The ESI is still a work in progress, but it has reached the point where it provides a credible measure of relative government performance on many of the short- and medium-term actions necessary to achieve environmental sustainability. With continued improvement, it will grow in validity and impact – perhaps someday becoming as important a measure as GDP in assessing national progress.

Box 5: Directions for Further Work: Data "Drill Down"

One of the remarkable stories behind the Information Age is how much environmentally relevant data and knowledge are being generated and shared without any plan, government mandate, or structured set of incentives to promote innovation. The ability to sift information is beginning to become as important as the capacity to gather it, beginning at the global level tackled by the ESI. This is particularly true for the quantitative performance measures that increasingly drive companies, communities, and even individuals to gauge their relative environmental performance against relevant peer groups. Even where government collects useful information, "hybrid" regulatory strategies may split responsibilities across two or more administrative levels, fragmenting data collection and leading to inconsistent data categories and collection methodologies. International collators of environmental data have, in particular, yet to "drill down" systematically to subnational sources where much of the most critical performance information is to be found.

In short, information sources change as decisionmaking becomes more market-oriented and decentralized, but by definition newcomers don't fit the organizing principles or "schema" previously designed to assist in the identification and classification of globally relevant information. Although designed for efficiency, these sorts of information-processing strategies often yield systematic and predictable errors which, when magnified on a global level, can severely distort both how nations approach environmental decisionmaking and how they analyze and discuss improvements to the global system of environmental indicators. The ESI counters this tendency by not only permitting but also encouraging change in technical details (both variables and how they are synthesized into indicators) on how to measure progress toward environmental sustainability.

This bottom-up, evolutionary approach to indicators takes more time and money than repetition of standard sources and methods. It also risks changing overall results so much that not only the ESI but the objectivity of indicators in general can be called into question. Fortunately, even changing a number of variables and adding several indicators produced relatively few major changes in country rankings between the 2005 ESI and the 2002 ESI. Nevertheless, one direction for further work centers on devising a more systematic approach to changing variables and justifying changes so the ESI can show where better environmental data needs to percolate up from decentralized and market-oriented decisionmaking processes.

Some environmental problems cannot be resolved by improving information flows among decisionmaking processes — or even by generation of more and better information. Improved data and information will not address questions of distributional equity. Nor will information fix human limitations with regard to risk perception. Nonetheless, the Information Age creates the possibility of reduced information gaps and restructuring institutional arrangements to form an environmental protection regime that is more refined, individualized, and efficient (Esty 2004). Realizing the possibility may require that national governments (and the international institutions they create) devise a decentralized and market-oriented information strategy that identifies gaps by origin (for example, technical and analytic barriers, market failures, and institutional shortcomings) and then decides who should fill them and who should pay. The ESI might become a catalyst for such a strategy, by going beyond the "wish list" of better indicators that has been given in reports to date. Such taxonomy would also help to connect indicators to actions, clarifying who should act and what might be done to effect progress on a particular variable or indicator.

Endnotes

¹ What we term Systems correspond to the DPSIR's State category. Our Stresses are largely the same as the Pressure measures, though we include a handful of Driving Forces, such as population growth rates. Our Vulnerability component corresponds closely with the DPSIR Impact category. In many ways, our Capacity component has much in common with the Response category of the DPSIR framework, but there is an important difference. The Response category typically is used to monitor deliberate social responses to environmental change, such as governmental policy or human behavior. It is usually seen as causally subsequent to the other elements of the DPSIR framework. In our case, we seek primarily to measure aspects of social and institutional capacity that will influence the nature of ongoing environmental change. Rather they include independent measures of social strength that in many ways will shape environmental outcomes. The Global Stewardship component has no simple counterpart in the DPSIR framework, but rather deploys some of its elements within the category of global responsibility.

Methodology

Considerable conceptual and analytical processing precedes the calculation of the ESI scores and rankings. The purpose of this Appendix is to provide detailed descriptions of the statistical techniques and methods used to calculate the ESI¹. Appendices C and D provide the data underlying the ESI. We offer this detail in support of the belief that transparency is an essential foundation for good analysis and policymaking.

The issues addressed here mirror those commonly encountered in the computation of composite indices: variable selection, missing data treatment, aggregation and weighting methodologies, as well as performance testing (OECD 2003).

In addition, the Appendix describes in greater depth the methods used in the statistical analyses that support the policy conclusions presented in the report. While the core text focuses on the key messages emerging from the analyses, this section includes the results of the ESI analyses and the relationships of the index to other key socio-economic and environmental benchmarks. The statistical procedures applied in the preparation of the 2005 ESI report include cluster analysis, principal component analysis as well as stepwise and multiple regression models.

The Appendix is organized into four sections. The first section provides step-by-step explanations of the construction of the 2005 ESI. It is divided into sub-sections, which describe:

- 1. The selection criteria for the countries included in the ESI.
- 2. The standardization of the variables for cross-country comparisons.
- 3. The transformation of the variables for the imputation and aggregation procedures.
- 4. The multiple imputations algorithm used to substitute missing data.
- 5. The winsorization of the data.

6. The aggregation of the data to indicator scores and the final ESI score.

The next section discusses the important issues of data quality and coverage and how we have managed them in the 2005 ESI. We include the "country data review," which was carried out to crosscheck our data and to increase temporal and spatial coverage. In addition to identifying the best available data for the 2005 ESI, we also explain the logic and motivation for assessing the quality of all datasets used and provide detailed information on their sources.

The uncertainty and sensitivity analysis carried out in collaboration with the Joint Research Centre of the European Commission is presented in the third section. In a significant move towards greater transparency, we evaluate the major sources of uncertainty in the ESI, including missing data treatment, aggregation, and weighting. Each source of potential uncertainty is tested individually as well as jointly to estimate the impacts on the country rankings. The results are used to emphasize key limitations in the accuracy of the ESI scores, to address methodological criticism levied at previous ESI releases, as well as to strengthen the scientific basis for the policy conclusions presented in the report.

Finally, in the fourth section, we offer more detailed descriptions and results of the statistical analyses that form the backbone of our policy conclusions. The statistical tools used include principal component analysis, stepwise regression, and cluster analysis.

Principal component analysis is used to investigate the number of distinct dimensions that exist within the ESI indicator matrix and to show the influence of the indicators along these dimensions. It is furthermore used to determine a set of weights for the 21 indicators based on their statistical importance. These statistical weights are then compared with the equal weights used in the 2005 ESI. In addition to identifying the most important indicators along the direction of the principal components, a stepwise regression analysis is conducted to determine the relative importance of the 76 variables with respect to the ESI score.

Because the ESI is a benchmarking tool for comparing national environmental stewardship, we emphasize the need to identify country peer-groups and "best practices" within those groups. We have conducted extensive cluster analyses, which identify relatively homogeneous seven country groupings with respect to the ESI indicators. This analysis brings to light several interesting patterns that cannot be attributed solely to the level of economic development. The characteristics with distinct patterns across the seven clusters, include population density, country size, and governance.

Calculating the ESI

1. Country Selection Criteria

A total of 146 countries met our inclusion criteria for the 2005 ESI. The decision to include a country in the index is based on country size, variable coverage, and indicator coverage as follows:

1. Country Size: Small countries are excluded. Countries with a total 2003 population under 100,000 or with land area under 5,000 square kilometers are excluded from the ESI because the nature of the interactions between elements of environmental sustainability are fundamentally different compared to larger countries. In particular, very small countries with large enough economies to be included in international data compilations resemble cities more than countries. They lack any sizable hinterland and have evolved to rely almost entirely on outsiders for provision of critical natural Such profound differences resources. make it difficult to justify including them in the same framework as other countries. However, separate ESI scores and component values for five small states are provided in Appendix E.

- 2. *Variable coverage:* While we seek to include as many countries as possible, the large number of missing observations makes it difficult to accurately and appropriately rank a country. We exclude countries that have observations for fewer than 45 of the 76 requisite data points for the ESI.
- 3. Indicator coverage: Some countries that survive the first two screens do not have even coverage across all 21 ESI indicators. We require that all countries in the ESI have observed variables for each of the ESI indicators, with two exceptions. Air Quality and Water Quality have relatively low country coverage across their constituent variables, but these indicators are judged too important to be eliminated. Because they are such vital issues, we want to retain the information we can for countries that report air and water quality, and we choose not to exclude the many countries that fail to report such data. If a country was missing *all* variables in *any* one of the remaining 19 indicators, it was removed.

2. Variable Standardization for Cross-Country Comparisons

To calculate the ESI scores for each country and to facilitate the aggregation of variables into indicators, the raw data need to be transformed to comparable scales. Some of the ESI variables already are denominated to make such cross-country comparison possible. Where this is not the case, we identify an appropriate denominator such as GDP, agricultural GDP, the total value of imports of goods and services, total population, the world average price of gasoline, city population, population aged 0-14 years, total land area, populated land area, as well as known amphibian, breeding bird, and mammal species.

3. Variable Transformation

After making the variables fit for crosscountry comparisons, the next step is to prepare them for the imputation and aggregation processes. The procedure spelled out below explains the data transformations undertaken prior to and after the imputations, as well as the impacts they may have on the Environmental Sustainability Index scores.

First, we test all variables for normality of distribution. In many cases, the observations exhibit substantial skewness (see formula below). Most variables also exhibit patterns of heteroskedasticity, which means that the variance of the observations increases with the magnitude of the data. Both interfere with the imputation model's assumption of multivariate normality.

$$S_{x_{j}} = \frac{1}{\sigma_{x_{j}}^{3}} \frac{\sum_{j=1}^{p} (x_{j} - \mu_{j})^{3}}{p}$$

A perfectly normally distributed variable is symmetric around its mean and hence has a skewness of zero. Skewed and/or heteroskedastic variables can be transformed to improve these properties but this may also change their distributions in ways that may affect the interpretation of the ESI scores. The logarithmic function, for example, is commonly used to reduce the influence of a few very large values by moving them closer to the mean. Similarly, it shifts very small values closer to the center of the distribution. Although the transformation may help approximating the normal distribution more closely, it will cause countries with exceptional values on a particular issue to no longer be such distinct outliers.

In addition to improving the imputation model, we also argue in favor of transformations as a means of reducing the impact of outliers on the ESI. In our experience, extremely small or large values have a relatively high probability of being measurement errors. A more normal, symmetric distribution implies that the majority of observations fall within two standard deviations of the mean (for a normal distribution, two standard deviations include 95% of the data) and extreme values occur with small probability.

However, in order to strike a balance between improving the distributional characteristics of the data and minimizing the impacts of the transformations on the ESI scores and ranks, we apply a 2-step procedure that recognizes the importance of normality for the imputations but its less significant value for the aggregation:

- 1. Prior to the generation of multiple imputations we transform all variables that have a skewness value larger than two using the base-10 logarithm or power transformations. In most cases the distributional effects of the transformations are beneficial.
- 2. After the imputations, we transform the variables back to their original scale with the exception of those variables with extreme skewness values of at least four (see Table A.1). In doing so, we ensure that only variables with extreme values outside four standard deviations are corrected for symmetry.

Variable	Variable Code	Transformation	Constant*
Urban population weighted SO ₂ concentration	SO2	Logarithm	0
Threatened mammal species as percentage of known mammal species in each country	PRTMAM	Logarithm	0
Freshwater availability per capita	WATAVL	Power 1/4	1

Carbon emissions per million dollars GDP	CO2GDP	Logarithm	0
Carbon emissions per capita	CO2PC	Logarithm	0

 Table A.1: 2005 Environmental Sustainability Index – Variable Transformations after Imputations

* If the observed minimum of the variable is negative, a constant is added such that the transformation of negative values can be computed. For example, if the minimum observed value is -5, a constant value of 6 is added to all observations before the logarithm or power transformation is computed.

4. Multiple Imputation of Missing Data

The question of how to treat missing or incomplete observations, which arise in virtually all types of environmental data collection, is among the most persistent and complicated problems facing policy analysts.

The degree of uncertainty due to the lack of data affects the ability to draw accurate conclusions and in many cases increases with the level of data aggregation. Insufficient data availability therefore has direct implications for effective and efficient decisionmaking.

We wish to minimize uncertainty and therefore attach substantial importance to the selection of the appropriate imputation method, i.e., the method used to fill data gaps with plausible estimates.

Two major assumptions are commonly made in the imputation literature:

- 1. The pattern of missing values in a multivariate vector of observations does not depend on the unobserved responses. In other words, the probability that a value is missing may be completely random (the statistical term is Missing Completely At Random or MCAR). Alternatively, it may depend on the observed values, which is called Missing At Random or MAR. The MAR assumption is more realistic for most real-life situations. If the parameters governing the missingness process are also independent of the parameters of the observed data model, the missing data mechanism is called "ignorable" and can be estimated.
- 2. A parameterized, functional form for the distribution of the vector observations can be formulated, and in most cases the estimates for the parameters of that form can be approximated using an iterative procedure (Johnson and Wichern 1998).

The following sections describe in detail how we selected and built the imputation model for the ESI.

Ad-hoc Methods v. More Sophisticated Approaches

The simplest ways of handling missing data are ad-hoc techniques such as *complete-case* and *available-case* methods (Little and Rubin 1987). The complete-case method uses only those observations for which all variables are observed. It is not applicable to the ESI because none of the 146 countries has observations for all 76 variables. We would hence be left with no observations in the imputation dataset.

The available-case method is based on analyzing subsets of the data for which all variables have been observed. For example, to impute missing water quality data using available cases, the imputation dataset could be limited to the water quality parameters only and all countries with one or more water quality parameters missing would be eliminated from this imputation dataset. Other variables are then imputed analogously.

It is apparent that both methods do not only lead to reduced ESI country coverage but also to potentially biased imputation results: both implicitly assume that the data are MCAR, which is highly improbable for the ESI data, because MCAR implies that all possible missingness patterns in the data matrix are equally likely.

Recognizing the complex relationships among the ESI variables we therefore opt for an imputation algorithm that broadens the base of actual experience, which allows us to involve as many countries as possible.

Table A.2 shows the top and bottom 20 countries in terms of data coverage. This list further corroborates that MCAR is not an appropriate model assumption for the ESI given the high correlation of data availability with level of income. We therefore investigated the use of a more sophisticated imputation model that does not require the

data to be separated into subgroups and allows for the less restrictive MAR assumption.

The statistical foundation for dealing with ignorable MAR processes was developed in the 1970s but has been integrated only recently into standard statistical software packages. The essential idea behind MAR is that the probability that an observation is missing may not be completely random but depend on other observed variables.

More formally, if r_{ij} denotes a missingness indicator for country *i* and variable *j*, which is 1 if the country *i* has an observation for variable *j* and 0 otherwise, and if the data matrix *X* is partitioned into observed, X_o , and missing data, X_m , then,

$$P(r_{ij} = 1 | X_o, X_m) = P(r_{ij} = 1 | X_o)$$

For example, if variable X_2 is not collected anymore and is hence missing once the value for variable X_1 has reached a certain level, the probability that X_2 is missing given the value of X_1 is determined by X_1 and is a MAR process. In Table A.2 we can see a correlation between income per capita and the number of observed values. There are many other cases in which GDP per capita is a strong predictor for the values of ESI variables, and we utilized these relationships in the imputation model by including GDP per capita as an ancillary variable (see also the section dealing with deciding which variable to impute for a list of other ancillary variables).

Although the MAR assumption is more suitable for the ESI, we cannot determine if the assumption holds or if the missing data follow a non-ignorable process, i.e., a process in which the probability of X_2 missing not only depends on X_1 but also on the missing value itself.

So far, we only considered replacing a missing value with a single, plausible alternative, but imputation procedures can also generate multiple substitutes for a missing value. The key idea behind multiple imputations is to create a finite number of m completed data sets, each of which is then analyzed using

Country	Observed	Missing	GDP / cap	Country	Observed	Missing	GDP / cap

standard statistical methods. The results of the *m* single analyses are combined to yield a final estimate of the parameter of interest. The advantage of using multiple imputations is that with repeated application of complete data analysis procedures, the uncertainty inherent in the imputation process can be captured in the variances within and between imputations.

We tested three different methods:

- 1. A simulation model using Markov Chain Monte Carlo (MCMC) techniques.
- 2. A regression-based modeling approach for missing data using observed values and existing correlations between the variables.
- 3. An Expectation-Maximization (EM) algorithm.

The Markov Chain Monte Carlo based imputation algorithm assumes multivariate normality of the data and generates imputations from the posterior distribution of the missing data given the observed data using a Bayesian approach. The missing data are presumed to be missing at random (MAR). Although in many cases the assumption of multivariate normality of the joint data distribution is not a realistic assumption, simulation tests have demonstrated relative robustness to deviations from this assumption (Little and Rubin 1987).

The regression imputation procedure is conceptually and computationally simple. Its underlying assumptions are that the marginal distributions of the data are normal and that linear relationships exist between the variables, which can be utilized for building linear regression models that predict the missing data. As with the MCMC model, the missing observations are assumed to be MAR.

The EM method uses an iterative process to estimate the mean vector and covariance matrix of the variables but does not generate multiple, independent draws from the data distribution. These can be obtained through the addition of a random noise, simulated from a specified distribution such as the standard normal distribution.

The relative usefulness of the three methods depends on the characteristics of the ESI data and the purpose of the analysis. Since we are interested in multiple imputations we eliminate the EM algorithm and compare the performance of the MCMC model with that of the regression model.

Comparison of Regression Imputation with MCMC Imputation

Using the ESI data, we generate imputations for both the MCMC and regression model and compare the results to see how robust the imputations and ESI scores and ranks are to the choice of imputation model. In general, we find that the differences in the results of the two methods with respect to the indicator values and ESI scores are limited, with a few exceptions. Table A.3 shows a sample of preliminary results for the ESI scores for both models using only ESI data in the first case and a set of additional socio-economic variables in the second.

Generally, we find that the inclusion of ancillary variables reduces the imputation variance of many variables that correlate with the additional data (for a list of ancillary variables refer to the sub-section Deciding Which Variables to Impute).

The ranks of the countries in the top and bottom quarter of the ESI appear to be relatively stable with only minor rank variation. Higher variation occurs in the middle 50% of the distribution. We attribute this in part to the heterogeneity of these countries with respect to environmental, institutional, and social circumstances and to the relative proximity of the ESI scores in the center of the ESI.

The deviation in means between variables imputed under the MCMC model and the regression model is higher when the fraction of missing data is large and when there are few comparable countries the imputation algorithm can build on to generate stable estimates. Variables that depend on largely unmeasured characteristics such as geography and climate are particularly affected. Such variables for which we do not have good "predictors" are used in the imputation model but are not imputed themselves (see Table A.4 for a complete list of not imputed variables.)

The relative robustness of the ESI ranks to the choice of imputation model, especially in the top and bottom quintiles, is further supported by the findings of the uncertainty and sensitivity analysis carried out with the Joint Research Centre of the European Commission, which is explained in the third section of this Appendix.

Although computationally more intensive, we use the MCMC method for the 2005 ESI because it provides the most flexible model for the ESI data and resulted in plausible imputations based on comparative tests among the three models. The exact procedure is described in the following section.

Table A.5: Impact of Imputation Model on 2005 ESI Kanks	Table A.3:	Impact of Imputation Model on 2005 ESI Ranks

Markov Chain Monte Carlo Simulation

Markov Chain Monte Carlo (MCMC) simulation substitutes missing values with plausible quasi-random draws from their conditional distribution given the observed data. The MCMC approach assumes an ignorable MAR process for the missing data generating mechanism. The full data set, Y, is assumed to have a well-specified distribution, generally a multivariate normal distribution, with independent and identically distributed, or *iid*, observations. The missing values are then imputed iteratively in a Bayesian framework using a sequence of Markov Chains. Let the observed data be denoted X_o and the missing data X_m so that the full data matrix is given by $X = \{X_o, X_m\}$. The algorithm is as follows:

- 1. Given a prior distribution for the parameters θ of the data model (in the case of the multivariate normal distribution the parameters are the mean and the covariance matrix) and an initial estimate of the parameters, $\theta^{(0)}$, the missing data, X_m , are imputed through random sampling from the conditional distribution of the missing data, X_m , given the observed data, X_o , and the initial parameter estimates.
- 2. The completed data set is then used to update the initial parameter estimate by sampling from the joint posterior distribution of the parameters given in the completed data set. The new parameter $\theta^{(1)}$ is then used to generate a new sample, $X_m^{(1)}$.
- 3. Iterating through steps 1 and 2 generates a Markov Chain of pairs of $(X_m^{(i)}, \theta^{(i)})$, which converges to the posterior conditional distribution of the missing data given the observed data. After a sufficiently long convergence time (burn-in), the first imputed data set can be drawn from the Markov Chain by sampling consecutively or every k^{th} draw (k > 0).
- 4. Steps 1 to 3 are then repeated *m* times to generate *m* imputed data sets.
- 5. The *m* data sets are then analyzed individually and their results combined to a final ESI score for each country. From the

m imputed data sets we can also obtain estimates of the standard errors of the missing data.

Number of Imputations

The larger the number of imputed values for each missing observation, the more that can be learned about the variation inherent in the missing observation. In the simplest case only one imputation (see single imputation methods discussed earlier) is generated. No statements can be made whether the substitute value is close to the "true" but unobserved value. The larger the number of imputations, the better our ability to estimate the variation and the more insight we have into the amount of missing information in the dataset and the band of uncertainty it creates.

Simulation studies have shown that for modest amounts of missing information (less than 30%), five to ten imputed datasets are sufficient to provide reasonable estimates of the parameters of interest.

Although we invested a great deal of effort in finding the most complete global data, the ESI still has approximately 18.6% empty cells in the data matrix. The amount of information missing may be somewhat higher depending on the importance of the variables with incomplete observations for determining a country's ESI. We therefore tested the robustness of the ESI by increasing the number of imputed datasets in our simulations from m=10 to m=30 and m=100.

With 30 or even 100 imputed datasets, it is possible to analyze not only the pattern of imputed values across countries for a specific variable, but also the distribution of the imputed values for a single country. We find that 30 sets of imputations provide a good compromise performance of the imputation model as well as computational efficiency.

Deciding which Variables to Impute

The ability of the imputation model to generate plausible and stable imputations depends not only on how well the data fit the model assumptions of MAR and multivariate normality but also on the inherent correlation structure.

For many aspects measured in the ESI we could identify predictor variables through correlation analysis. In addition to the existing observations for each variable, the observations of the predictors assist the model in generating more reasonable values. But we do not rely on the ESI variables alone. Previous releases of the ESI have already pointed out that certain ancillary variables such as transformations of GDP per capita, area, and population density can help to further fine-tune the predictions.

We therefore identified and include the following ancillary variables: populated land area (at least 5 persons per square kilometer), square of the base-10 logarithm GDP per capita, base-10 logarithm GDP per capita, health expenditure per capita, high technology exports as percentage of total exports, base-10 logarithm of total area, arable land as percentage of total land, base-10 logarithm of population, base-10 logarithm of population density, trade as percentage of GDP, and memberships in the Organisation for Eco-**Co-Operation** and nomic Development (OECD) and the Organization of the Petroleum Exporting Countries (OPEC). All data except for the populated land area dataset are from the World Bank's *World Development Indicators*.

Based on 30 fully imputed datasets, we compare the performance between imputations to check if the imputed values are stable. This is not the case for all variables. Variables that depend heavily on conditions not captured by the ESI or the ancillary variables, such as climatic, geographical, and many ecological factors, perform inadequately in the imputation model. These variables are therefore not imputed but used to assist in imputing missing values for variables that the ESI data and external data could impute in a stable manner. Table A.4 lists the variables that are not imputed.

In particular, we excluded Suspended Solids and SO_2 Exports from imputation because the results are too volatile and the fraction of missing values is large for both. We do not have sufficient confidence in being able to estimate their missing values with acceptable accuracy.

The final dataset is then obtained as the average of all values in each cell in the data matrix.

Table A.4: List of Variables not Imputed

Indicator	Variable	Code	Logic for not imputing
	National Biodiversity Index	NBI	Dependence on ecological and geographi- cal factors not captured in ESI
	Percentage of country's territory in threatened ecoregions	ECORISK	Dependence on ecological and geographi- cal factors not captured in ESI
Biodiversity	Threatened mammal species as percentage of known mammal species in each country	PRTMAM	Dependence on ecological and geographi- cal factors not captured in ESI
	Threatened bird species as percentage of known breeding bird species in each country	PRTBRD	Dependence on ecological and geographi- cal factors not captured in ESI
	Threatened amphibian species as percentage of known amphibian species in each country	PRTAMPH	Dependence on ecological and geographi- cal factors not captured in ESI
Water Quality	Suspended solids	WQ_SS	High volatility of imputation results and dependence on factors not captured in the ESI
Water Quantity	Freshwater availability per capita	WATAVL	Dependence on ecological and geographi- cal factors not captured in ESI
Water Quantity	Internal groundwater availability per capita	GRDAVL	Dependence on ecological and geographi- cal factors not captured in ESI
Reducing Waste and Consumption	Generation of hazardous waste	HAZWST	Whether a country generates hazardous waste depends on factors not captured by the ESI.
Pressures	Waste recycling rates	RECYCLE	The data set is merged from two different sources, imputations would not be interpretable
Reducing Water Stress			Dependence on ecological and geographi- cal factors not captured in ESI
	Productivity overfishing	OVRFSH	Dependence on ecological and geographi- cal factors not captured in ESI
Natural Resource Management	Salinized area due to irrigation as percentage of total arable land	IRRSAL	Dependence on ecological and geographi- cal factors not captured in ESI
	Agricultural subsidies	AGSUB	Lack of information on external factors determining this variable
Reducing Environment-Related	Average number of deaths per million inhabitants from floods, tropical cyclones, and droughts	DISCAS	Dependence on ecological and geographi- cal factors not captured in ESI
Natural Disaster Vulnerability	Environmental Hazard Exposure Index	DISEXP	Dependence on ecological and geographi- cal factors not captured in ESI
	Local Agenda 21 initiatives per million people	AGENDA21	Lack of information on external factors determining this variable
	Civil and Political Liberties	CIVLIB	Complete coverage
Environmental Governance	Percentage of variables missing from the CGSDI "Rio to Joburg Dashboard"	CSDMIS	Information which variables from the CSD CG list are missing cannot be imputed
	Knowledge creation in environmental science, technology, and policy	KNWLDG	Lack of information on external factors determining this variable
	Democracy measure	POLITY	Lack of information on external factors determining this variable
Eco-efficiency	Hydropower and renewable energy production as a percentage of total energy consumption	RENPC	Renewable energy sources depend on geography, climate, and other factors not captured by the ESI
	Dow Jones Sustainability Group Index (DJSGI)	DJSGI	Not applicable
Private Sector	Average Innovest EcoValue rating of firms headquartered in a country	ECOVAL	Not applicable
Responsiveness	Number of ISO 14001 certified companies per billion dollars GDP (PPP)	ISO14	Not applicable
	Participation in the Responsible Care Program of the Chemical Manufacturer's Association	RESCARE	Not applicable
Participation in International	Number of memberships in environmental intergovernmental organizations	EIONUM	Not applicable
Collaborative Efforts	Participation in international environmental agreements	PARTICIP	Not applicable
Reducing Transboundary Environmental Pressures	SO ₂ Exports	SO2EXP	Dependence on factors not captured in the ESI such as prevailing winds and geographical location

5. Data Winsorization

Following imputations, we "winsorize" or trim the tails of the variable distributions. Winsorization corresponds to shifting observations in the tails of the distribution to specified percentiles.

The purpose of the winsorization is to avoid having a few extreme values overly dominate the aggregation algorithm. We apply winsorization because we believe that such extreme values are more likely to reflect data quality problems in the tails of the distribution as opposed to values closer to the center of the distribution.

For each variable, the values exceeding the 97.5 percentile are lowered to the 97.5 percentile. Similarly, values smaller than the 2.5 percentile are raised to the 2.5 percentile.

Although we apply the transformation to every variable, the total number of affected values is very small. As another quality check on the imputations, we verified whether variables with imputed values have a higher degree of observations in the extreme tails. We observe a small, significant correlation between the number of winsorized values and the number of data points imputed for the 97.5% percentile, indicating that the imputation is more likely to generate large outliers than small outliers (see Table A.5).

The ESI could be criticized for using winsorization because it changes the distribution of the variable and either benefits or penalizes countries with values outside the center 95%. But our finding that winsorization affects only a very small fraction of the data and correlates with the imputations only to a small extent convinces us believe that its benefits outweigh this potential drawback. The Uncertainty and Sensitivity Analysis in Section 3 provides further support for this methodological decision.

6. Data Aggregation and Weighting

Aggregation

Composite indices are aggregations of sets of variables for the purpose of meaningfully condensing large amounts of information. Various aggregation methods exist and the choice of an appropriate method depends on the purpose of the composite indicator as well as the nature of the subject being measured.

The most common types of indices used are weighted sums and weighted geometric means of sub-components. The ESI belongs to the first group because it is the equally weighted sum of the 21 indicators:

$$I_i = \sum_{j=1}^p w_j \widetilde{X}_j \qquad i = 1, \dots, n,$$

where w_j is the j^{th} weight given to \widetilde{X}_j , which corresponds to the z-score of the j^{th} indicator. Each indicator is itself a weighted sum of the 2 to 12 underlying variables. Within each indicator the variables are also weighted equally.

Weighted summations, in the form of averages, are not necessarily scale invariant. That means that the resulting index value, I_i , for the i^{th} object depends on the scales of the variables aggregated in the index.

 Table A.5: Correlation between Number of Imputations and Number of Winsorizations.

	Number of Imputations					
Winsorization	Pearson	Kendall's Tau	Spearman's Rho			
2.5 Percentile	0.16	0.12	0.18			
97.5 Percentile	-0.25*	-0.20*	-0.24*			
2.5 and 97.5 Percentile	0.06	0.03	0.04			

* Correlation is significant at the 0.05 level (2-tailed).

Multiplicative expansions from one scale to another, for example, are abundant in the environmental domain. Because of this, the construction of indices based on weighted summation needs to take into account the possibility that the index values may change depending on the scale used.

The aggregation therefore requires that the $(n \times p)$ matrix X of n countries and p variables is normalized, i.e., all variables are on the same scale, in order to avoid distortions due to variables with very large values or variances. Most economic indices are built on a monetary unit of measurement, which provides a unified framework for comparing country performance. Environmental data do not generally have a common scale and normalization is necessary to remove the scale effects of different units of measurement without changing the relative distances between observations.

The ESI preserves the relative distances between countries' values by converting all variables to z-scores, which are obtained by subtracting the mean from the observation and dividing the result by the standard deviation of the variable. For variables in which high values correspond to low levels of environmental sustainability, we reverse the order by subtracting the observation from the mean and dividing the result by the standard deviation. In other words, for variables such as "percentage of land area under protected status" we use the conventional z-score, whereas for variables such as "percentage of mammals threatened" we produce a z-score in which higher percentages of threatened mammals correspond to lower levels of environmental sustainability.

Although normalization of the variables to zscores removes the scale effects, z-scores depend on observed data statistics. They are "relative transformations" and change every time the ESI is updated due to shifts in the distribution of the variables over time. Furthermore, if all countries improve their performance on a given variable by the same amount between two time periods, the z-scores will remain the same even though performance has improved across the board.

The relationship among the variables and their individual contribution to the ESI merits significant attention. Linear weighted summavariables tion implies that the are preferentially independent (Munda and Nardo 2003b). Preferential independence means that the trade-off ratio between any two variables in a set, \wp , of variables is independent of the values taken on by the variables in \wp^{c} (the complement of \wp). Under preferential independence, the summation of variables in the ESI corresponds to their marginal contributions to environmental sustainability, and requires that there are no synergistic or antagonistic effects among the variables. This is hardly a realistic assumption for environmental data. Given, for example, the proven synergistic relationships between several SO₂ and NO_x in the formation of acid rain, we cannot realistically assume preferential independence.

Weighted geometric mean aggregation is a potential alternative. It is defined as

$$I_{i} = \prod_{j=1}^{p} (w_{j}X_{j})^{1/p} \quad i = 1, ..., n$$

Ebert and Welsch demonstrate that in the case of strictly positive, ratio-scale noncomparable variables, including many environmental variables, the aggregation by geometric mean can provide meaningful indices, i.e., indices with unambiguous orderings (Ebert and Welsch 2004). Another, more advanced approach is the multi-criteria decision method, which does not allow poor performance on one variable to be compensated by good performance on another.

When comparing the properties of the three different aggregation methods, the trade-offs become clear. When the objective is to design the best possible index, considerations of the most advanced statistical techniques available are important. On the other hand, if transparency and easy understanding by non-experts is equally important, the logical framework of the ESI represents a useful and valid alternative.

In an important expansion of our analysis of the properties of the ESI, we include in this Appendix the uncertainty and sensitivity analysis of the ESI, carried out by the Joint Research Centre of the European Commission in Ispra, Italy. The analysis identifies and quantifies the impact of the different sources of uncertainty in the ESI data as well as the effects of the weighting and aggregation methods on the rankings of the ESI.

Weighting

In composite indices, the choice of weights can reflect the importance given to the variables comprising the index or the substitution rates between them. In other instances, the weights are used to adjust for unequal variances of the variables, and hence their unequal levels of certainty. The specification of the weights is thus an integral part of index development and below we discuss our logic and motivation for choosing equal weights for the 21 indicators in the ESI.

Different methods to determine weights have been developed. They include data-dependent statistical tools as well as judgment-based expert opinions and budget allocation schemes.

Relative weights can be derived from least squares estimation, i.e., the line fitting method that minimizes the sums of squares of the relative distances of points from their expected value. Least squares minimization is the procedure underlying the linear regression model. A frequently occurring problem in least squares is that larger values tend to be associated with larger standard errors. Large observations will therefore have a disproportional influence on the sum of squares compared to smaller values. A weighted least squares approach corrects for this effect.

Principal component analysis and factor analysis are also useful statistical tools for estimating weights. They build on the relative importance of the variables for the principal components.

Statistically determined weights have the advantage that they apply a neutral and datareliant weighting. However, statistical weights do not always reflect the priorities of decisionmakers or the budget constraints that limit free choice among a range of policy options.

Various methods for eliciting subjective preferences have been developed using elements ranging from budget allocation techniques to correspondence analysis. Regardless of whether the weights are determined statistically or subjectively, in most cases there exists no unique set of weights.

The ESI uses equal weights at both the indicator and the variable level. Our argument for equal indicator weights is based on the premise that no objective mechanism exists to determine the relative importance of the different aspects of environmental sustainability. At the country level, the indicators would almost certainly be weighted differently, but we cannot determine a globally applicable, differential set of weights that would allow a fair comparison between countries. As unsatisfactory as the choice of equal weights may appear, it is a neutral and justifiable allocation of importance across the indicators. Moreover, the principal component analysis in section 4 demonstrates that, even if the weights are determined through statistical means, no indicator stands out as being more or less important than others.

The variables within each of the 21 indicators are equally weighted because we think that each variable contributes roughly proportionately to the indicator to which it is allocated. In cases in which a country is missing a variable (and it is not imputed), the variable is not included in the average.

We note here that an interactive form of the ESI, that allows the user to set his or her own weights and to re-calculate an ESI based on these weights, is under development and will be made available on our website.

Data Quality and Coverage

1. Variable Grading

One of the most important conclusions of the ESI is the need for better data and a policy commitment to developing the necessary analytic underpinnings for a more data-driven approach to environmental decisionmaking. To further facilitate this process, we evaluated all ESI data sets with respect to the following criteria:

Relevancy:

1. The degree to which the variable matches the issue of interest.

Accuracy:

- 1. The reliability of the data source.
- 2. Whether the variable methodology is well established and widely adopted.
- 3. The availability of other data for crosschecking to assess the accuracy of the variable.

Coverage in space and time:

- 1. The availability of the most recent data.
- 2. The frequency with which the variables are updated.
- 3. The spatial coverage of the variable.
- 4. Whether the time series data can be constructed.

Certain variables are based on more than one data source, in which case, each data source is

rated separately. In most cases, there are no deviations between the ratings of the sources. In the few instances where they are judged differently, this has been marked.

The evaluation of the variables was conducted by team members at the Yale Center for Environmental Law and Policy and Columbia University's Center for International Earth Science Information Network and combined into a single rating. The participants of the 2005 ESI Expert Review Meeting in December were also asked to comment on the preliminary "grades" and evaluations.

The evaluation process is inescapably subjective and limited by the knowledge base of the research teams. The goal of this exercise is not to establish a definitive quality assessment for each dataset, rather it is to begin a dialogue about data quality and to encourage further investments in data collection and methodological improvements. The grading scale used for the evaluation rates each variable according to its relevancy, accuracy, and coverage in space and time using grades ranging from A (Excellent) to F (Unacceptable), or U (Unknown).

The resulting matrix of variable grades summarizing our assessment of the relevancy, accuracy, and coverage of the variables in the ESI is shown in Table A.6.

Component	Indicator Number	Indicator	Variable Number	Variable			Reliability of data source	Variable methodology	Cross-check criteria	Most recent data set	Frequency of update	Spatial coverage	Consistent time series
			1	NO2	Urban population weighted NO ₂ concentration	А	А	В	С	A-	A-	D	B-

2. Country Data Review Initiative

One of our main objectives is to advance the global availability of reliable, timely, and comparable environmental information for environmental decisionmaking.

For this purpose, we provided our updated data for the 2005 ESI to the environmental ministries and statistical offices of 152 countries, requesting that they review the data for accuracy and provide, where applicable, corrections or recent updates.² We also set up a website through which we were able to provide regular updates and additional information on the ongoing data review process. A total of 62 countries responded to our request. Of these, 25 countries sent us updated and additional data and 14 provided useful feedback on methodological aspects of the ESI. Thirty-nine of the countries also sent us references to reports and websites or informed us that they had no comments on the data we sent (see Table A.7 for a detailed list of responses).

We also made it clear in our data review that we support the established environmental data collection activities of international institutions, especially the United Nations system of data collections, and requested that responses also be submitted to the respective international organizations compiling the statistics.

We utilized all information from the responses that was consistent with our methodology. Through the metadata provided by countries and follow-up communication with our contacts in the countries we were able to determine the consistency of the data with those provided by international sources. Table C.1 in Appendix C – Variable Profiles provides source information, including country sources where country data were incorporated, for all variables.

3. Search for Additional and Better Data

In our attempt to update the ESI with the most recent, comparable, and high-quality data, we searched extensively for data to both improve current proxy variables in the ESI and to fill important gaps in the range of environmental, socio-economic, and institutional topics that the ESI indicators cover.

We carefully reviewed critiques of previous ESI reports and addressed a range of peer review comments to identify issues that are not adequately addressed by the ESI. An important outcome of this review and analysis is the revision of the ESI structure. The 2005

ESI includes 14 new variables, which are allocated to an improved 21-indicator framework. Two indicators - Natural Resource Management and Reducing Environment-Related Natural Disaster Vulnerability - have been added to the 2005 ESI. The Capacity for Debate indicator used in the 2002 ESI has been folded into the Environmental Governance indicator as we became convinced that they track the same phenomenon. The description and logic for each variable is given in Table A.8 while Table A.9 explains the replacements and deletions we have made in the variable composition.

Variable	Variable Description	Units	Logic
AGENDA21	Local Agenda 21 initiatives per million people		Local Agenda 21 (LA21) is an international sustainability planning process that provides an opportunity for local governments to work with their communities to create a sustainable future. The number of Local Agenda 21 initiatives in a country measures the degree to which civil society is engaged in environmental governance.
AGSUB	Agricultural subsidies	Percentage of total agricultural GDP (USD) that comes from subsidies	Agricultural subsidies reduce environmental sustainability primarily by creating price distortions, promoting the production of input intensive crops, wasteful use of natural resource inputs; use of marginal and fragile lands, and rent-seeking behavior.
DAI	Digital Access Index	Score between 0 and 1 with higher scores corresponding to better access	The Internet has created a new economy and promoted an unprecedented increase in the amount of environmental information that can be accessed and disseminated worldwide. Access to the Internet thus is important for access to information, stakeholder participation, decisionmaking, and generation of innovative solutions to environmental problems.
DISCAS	Average number of deaths per million inhabitants from floods, tropical cyclones, and droughts	Average number of deaths per million inhabitants	Vulnerability to natural disasters is a function of the severity of the hazard and the resilience of the socioeconomic system to perturbations. High vulnerabil- ity, as reflected in large numbers of disaster-related casualties, affects a country's ability to achieve longer-term sustainable development by redirecting resources to disaster recovery and reducing future resiliency.
DISEXP	Environmental Hazard Exposure Index	Average number of hazards to which the population is exposed (between 0 and 4)	Vulnerability to natural disasters is a function of the severity of the hazard and the resiliency of the socioeconomic system to perturbations. High exposure to natural hazards means that resources that could be used to achieve longer- term sustainable development must either be used for preventative measures or for disaster response.
FORCERT	Percentage of total forest area that is certified for sustainable management	Percentage of total forest area that is FSC or PEFC certified	This variable measures the extent to which a country seeks sustainable forestry practices.
GOVEFF	Government effectiveness	Z-score with high values corresponding to high levels of effectiveness	Governmental Effectiveness is defined in this data set as "quality of public service provision, the quality of the bureaucracy, the competence of civil servants, the independence of the civil service from political pressures, and the credibility of the government's commitment to policies." It is relevant for environmental sustainability because basic governmental competence enhances a society's ability to monitor and respond to environmental challenges.
GRDAVL	Internal ground water availability per capita	Thousand cubic meters per capita	Surface water is an important part of the picture of a country's water resources. The more groundwater is available per capita, the higher the probability that a country can sustainably manage its groundwater resources, e.g. for agricultural production.
INDOOR	Indoor air pollution from solid fuel use	Percentage of households using solid fuels, adjusted for ventilation	The public health community has drawn attention to the deleterious effects of indoor air pollution, especially on women who cook inside using solid fuels. High exposure to the fumes from solid fuel combustion is dangerous to human health. Solid fuel use has further consequences for deforestation and soil depletion because of dung collection.
IRRSAL	Salinized area due to irrigation as percentage of total arable land	Percentage of total arable land salinized due to irrigation	Soil salinization is a form of land degradation. The transport of salts to the land's surface due to irrigation renders the land unfit for production, and is therefore unsustainable in the long-term.
LAW	Rule of law	Z-score with high values corresponding to high degrees of rule of law	The rule of law is important in terms of establishing the "rules of the game" for the private sector, and for ensuring that violations of environmental regulations are enforced.
OVRFSH	Productivity overfishing	Score between 1 and 7 with high scores corresponding to overfishing	Overfishing of a country's exclusive economic zone is unsustainable.
POLEXP	Import of polluting goods and raw materials as percentage of total imports of goods and services	Import of polluting goods and raw materials as percentage of total imports of goods and services	Countries that import a large volume of commodities that are associated with negative environmental externalities at the point of extraction or processing may not be pursuing an environmentally sustainable path because of the likelihood that their actions are contributing to damage abroad. This measure does not take into account variation in actual environmental externalities within exporting countries, nor does it factor in other relevant imports that are not classified as commodities; as such it should be considered a rough proxy.
RESEARCH	Number of researchers per million inhabitants	Number of researchers per million inhabitants	Scientific capacity is important for the development of new technologies for sustainable environmental management.

 Table A.8: Variable Additions to the 2005 ESI (alphabetical order)

The new variables greatly strengthen the ESI's capacity to assess key aspects of environmental sustainability. The gains emerge in some cases through better measures such as the Digital Access Index, which replaces the Number of Internet Hosts per million Inhabitants, or through incorporating a policy element that was previously unaddressed, such as Agricultural Subsidies as a proxy for agricultural sustainability and Indoor Air Pollution from Solid Fuel Use as a proxy for air quality.

In some cases, the new datasets are only rough gauges of issues we wish to track, e.g., overfishing and agricultural subsidies. But they reflect our best effort to produce a useful assessment of very complex concepts and to capture critical dimensions of sustainability that are often difficult to measure.

For other ESI variables, we could not identify better measures but succeeded in improving their geographical coverage by merging several data sources. In this context, several water and air quality variables were supplemented with information from additional sources. Despite their crucial influence on public health, infrastructure, and associated economic impacts, a real shortcoming exists with respect to ambient air pollution and water pollution. If it were not for their importance, the variables allocated to these two indicators would not have met our criteria for inclusion in the Index.

Table A.9: Summary of Changes in Variable Com	position
Variable Replacements	
New in 2005 ESI	Previously in 2002 ESI
Percentage of variables missing from the CGSDI "Rio to Joburg Dashboard"	Percentage of ESI variables in publicly available data sets
Generation of hazardous waste	Radioactive waste
Gross tertiary enrollment rate	Technology Achievement Index
Digital Access Index	Technology Achievement Index
Percentage of total forest area that is certified for sustainable management	FSC accredited forest area as percent of total forest area
Female primary education completion rate	Technology Achievement Index
Participation in international environmental agreements	Percentage of CITES reporting requirements met; Participation in Vienna Convention / Montreal Protocol; Participation in Climate Change Convention
Contribution to international and bilateral funding of environmental projects and development aid	Global Environmental Facility participation; Participation in Montreal Protocol multilateral fund
Freshwater availability per capita	Internal renewable water per capita; Per capita water inflow from other countries
New or Additional Variables or Data Sources	Logic
National Biodiversity Index	Improving the Biodiversity indicator
Percentage of country's territory in threatened ecoregions	Improving the Biodiversity indicator
Threatened amphibian species as percentage of known amphibian species in each country	Improving the Biodiversity indicator
Knowledge creation in environmental science, technology, and policy	Knowledge generation in environmental science and policy facilitates development of innovative environmental technologies and policies
Participation in Responsible Care Program of the Chemical Manufacturer's Association	Voluntary and self-regulatory program of the chemical industry that, albeit non-binding, demonstrates willingness of private sector to take more responsibility for environmental protection and resource management
Waste recycling rates	Waste and consumption intensities can be counter-balanced by high resource recycling rates

 Table A.9: Summary of Changes in Variable Composition

Table A.9 continued on next page

New or Additional Variables or Data Sources	Logic
Dissolved oxygen	Increasing geographical coverage
Electrical conductivity	Increasing geographical coverage
Phosphorus concentration	Increasing geographical coverage
Suspended solids	Increasing geographical coverage
Anthropogenic SO_2 emissions per populated land area	Increasing geographical coverage
Anthropogenic NO _x emissions per populated land area	Increasing geographical coverage
Anthropogenic VOC emissions per populated land area	Increasing geographical coverage
Agricultural subsidies	Important proxy for measuring sustainable agricultural practices
Productivity overfishing	Important proxy for measuring sustainable fisheries management
Local Agenda 21 initiatives per million people	Gauges country's capacity and ability to implement sustainable development strategies at the local level
Average number of deaths per million inhabitants from floods, tropical cyclones, and droughts	Assessing a country's vulnerability to environmental disasters
Environmental Hazard Exposure Index	Assessing a country's vulnerability to environmental disasters
Government effectiveness	Effective government is important for sustainable natural resource use and management
Internal groundwater availability per capita	Supplementing surface water availability
Indoor air pollution from solid fuel use	Indoor air quality is at least as important an environmental health factor as ambient air quality
Salinized area due to irrigation as percentage of total arable land	Proxy for sustainable agricultural practices
Rule of law	Effective law enforcement is important for sustainable natural resource use and management
Number of researchers per million inhabitants	Gauges a country's capacity to generate and adopt innovative technologies and to implement them
Variables deleted	Logic
World Business Council on Sustainable Development memberships	Memberships do not imply tangible actions by private sector
CFC Consumption	CFC consumption successfully regulated under Vienna Convention and Montreal Protocol (and Amendments)
Subsidies for commercial fishing sector	Important but outdated data set
Total marine fish catch	Inadequate measure of transboundary pressure
Seafood consumption per capita	Inadequate measure of transboundary pressure

One solution to the problem of insufficient national data is to use modeling data. If the phenomenon of interest is regional or global in scope, complex modeling systems built on observed input data, for example meteorological records, can achieve astonishing accuracy. The ESI used data from several widely accepted models. The variables for which we adopted model estimates are water availability and water stress (WaterGap model version 2.1e, Kassel University, Germany), excessive (Stockholm acidification Environment Institute at York), long-range air transport of sulfur dioxide (Europe's EMEP program and IIASA), anthropogenic emissions of NO_x, SO₂, and VOCs modeled by the Intergovernmental Panel on Climate Change (IPCC), and

populated land area measured as the area of a country with a population density of at least 5 people per square kilometer. This data set was constructed by CIESIN as part of the Gridded Population of the World GPW version 3 program using nine geospatially referenced input data sets.

Finally, we also received custom-made data sets from two private entities that evaluate corporate sustainability: the EcoValue21 rating from Innovest and the Dow Jones Sustainability Index from the Dow Jones Sustainability Group. These data sets have real limitations as proxies for private sector contributions to environmental sustainability. Notably, they are oriented to the environmental stewardship of large companies and are thus likely to be skewed toward efforts in the developed world. We include these variables to highlight the central role of business in the quest for environmental progress in every society. However, finding better ways to gauge private sector environmental performance must be seen as a high priority.

Despite our efforts to find data or build our own measures, persistent shortcomings exist with respect to long-term local, regional, and global environmental processes such as the evolution of biological diversity in ecosystems, the flux, dispersion, and deposition of long-range air pollution, and the monitoring of global weather, hydrological, and climate processes. Enormous scientific progress has been made in understanding the functioning of these systems. However, global data availability is lagging behind. We believe that the Environmental Sustainability Index could be improved by including data on several variables, all of which are believed to have significant impact on natural resource use, human health, and ecosystem resilience. Among these variables are emissions of Persistent Organic Pollutants (POPs) as well as emissions of mercury and lead. However, we decided not to include any information on these variables in the Index because of their lack of sufficient quality and coverage. Other measures of importance but lacking data include toxic and solid waste management, wetlands loss, nuclear reactor safety, and sustainable agricultural practices.

Uncertainty and Sensitivity Analysis of the 2005 ESI

Prepared by Michaela Saisana, Michela Nardo, and Andrea Saltelli (Applied Statistics Group), Joint Research Centre of the European Commission

Sensitivity analysis is the study of how output variation in models such as the ESI can be apportioned, qualitatively or quantitatively, to different sources of variation in the assumptions. In addition, it measures how the given composite indicator depends upon the information that composes it. Sensitivity analysis is closely related to uncertainty analysis, which aims to quantify the overall variation in the countries' ranking resulting from the uncertainties in the model input.

A combination of uncertainty and sensitivity analysis can help to gauge the robustness of the ESI, to increase its transparency, and to frame policy discussions. The validity and robustness of the ESI depends on a number of factors including:

- The model chosen for estimating the measurement error in the data, which is based on available information on variance estimation.
- The mechanism for including or excluding variables in the index.

- The transformation and/or trimming of variables during the construction process of the index.
- The type of normalization scheme, such as re-scaling or standardization, applied to remove scale effects from the variables.
- The amount of missing data and the choice of imputation algorithm, in this case Markov-Chain Monte Carlo (MCMC) simulations or the EM algorithm.
- The choice of weights, e.g., equal weights or weights derived from factor analysis and expert opinion models.
- The level of aggregation, at the indicator or the component level.
- The choice of aggregation system, e.g., additive, multiplicative, or multi-criteria analysis.

All these assumptions can heavily influence the ESI country rankings and should be taken into account before attempting an interpretation of the results. The Joint Research Centre of the European Commission in Ispra, Italy, systematically evaluated the impacts that the above conceptual and methodological choices have on the robustness of the ESI ranking using uncertainty analysis and sensitivity analysis.

Among the chief questions in assessing the robustness of the ESI ranking is how sensitive it is to changes in its structure and aggregation.

While uncertainty arises from all of the items listed above only some are significant and can be measured. The measurement error is unknown for virtually all variables, and the inclusion criteria, transformations and winsorization, and normalization to z-scores were found to negligibly change the country ranks. They are thus excluded from the results presented in this Section.

The output of interest in all tested scenarios of the sensitivity analysis is each country's rank. This is denoted $Rank_c$ for c = 1,...,146. The

average shift, \overline{R} , in the ranks across countries, is calculated as the average of the absolute differences in countries' rank with respect to the original ESI rank:

$$\overline{R} = \frac{1}{146} \sum_{c=1}^{146} \left| Rank_{ESI2005,c} - Rank_c \right|$$

We analyzed the following issues:

- 1. How do the ESI 2005 ranks compare to the most likely rank under all scenarios?
- 2. What is the optimal scenario for each country?
- 3. Which are the most volatile countries and why?
- 4. What are the major sources of volatility in the ranking?

The sensitivity analysis procedure is a simulation-based procedure that acts on the equations that create the ESI model. Each equation corresponds to one step in the ESI construction. Although a range of methods exists for evaluating output uncertainty (Saltelli, Chan et al. 2000) we choose a Monte Carlo approach because it considers all uncertainty sources simultaneously. The simultaneity of the approach allows us to capture all possible synergistic effects among uncertain input factors, including their interactions as well as individual effects.

1. Our Approach

All uncertainties are then translated into a set of scalar input factors, which are sampled from their distributions (discrete in the case of triggers, or continuous in the case of imputed data). We specified the following inputs of uncertainty:

- 1. Imputation: We consider the variance associated with the m=30 fully imputed datasets that are generated for each missing datum to construct a distribution centered around the mean. This allows us to study the effect of imputation variability on the ESI ranking.
- Weighting schemes: We consider an expert opinion model as an alternative weighting scheme to the equal weighting approach used in the original ESI. A sample expert rating of a set of ESI indicators was obtained by averaging the opinion from 17 experts working on a broad spectrum of environmental sustainability and policy issues. (1)
- 3. Aggregation level: We studied the impact of aggregation at the level of the five components compared to the 21 indicators in the original ESI.
- 4. Aggregation method: We compare the ESI's linear aggregation model with a non-compensatory multi-criteria model to account for the compensability issue among indicators.

By sampling the input space we obtained some N=10,000 combinations of the 4 independent input factors \mathbf{X}^{l} , l=1,2,...N, where N corresponds to the total number of simulations. For each trial sample \mathbf{X}^{l} , the ESI was computed, generating values for the scalar output variable of interest Y^{l} , where Y^{l} was either $Rank_{c}$, the rank assigned by the index to each country, or \overline{R} , the averaged shift in

countries' rank. Each output vector, \mathbf{Y}^{l} , is then associated with the corresponding generating input vector \mathbf{X}^{l} .

For the choice of sampling method we consider simple random sampling, stratified sampling, quasi-random sampling and others (Saltelli, Chan et al. 2000). We use the sampling strategy based on Sobol sequences vectors (LP_{τ} sequences, (Sobol 1967)), which are quasi random sequences, to produce sample points that best scan the entire space of possible combinations between the input factors (Sobol 1976). Quasi-random sequences are used in place of random points to guarantee convergence of estimates. Moreover, Sobol sequences usually result in better convergence when employed in numerical integration. Bratley and Fox provide a good summary description (Bratley and Fox 1988).

The sequence of \mathbf{Y}^t allows estimation of the empirical probability distribution function (pdf) of the output Y. The distribution reflects the uncertainty of the output due to the uncertainty in the input. Its characteristics, such as the variance and higher order moments, can be estimated with an arbitrary level of precision that only depends on the number of simulations, N.

The present analysis models several inputs of uncertainty simultaneously, which causes the index to be non-linear (Saisana, Tarantola et al. 2005). As argued by practitioners (Saltelli, Tarantola et al. 2000; EPA 2004), robust, "model-free" techniques for sensitivity analysis should be used for non-linear models.

Variance-based techniques for sensitivity analysis are model free and display the following additional properties convenient for the present analysis:

- Exploration of the whole range of variation in the input factors, instead of only sampling factors over a limited number of values, as done in fractional factorial design (Box, Hunter et al. 1978);
- Distinguish main effects (first order) and interaction effects (higher order);
- Easy interpretation and explanation;

- Simultaneous consideration of uncertainty factors;
- Justification of rigorous settings for sensitivity analysis, as is discussed later in this section.

2. Results and Discussion

1. How do the ESI 2005 ranks compare to the most likely ranks under all scenarios?

The uncertainty analysis results of the 146 countries ranks are given in Figure A.1. Countries are ordered by their original ESI 2005 rank.

The original ESI ranks (grey mark) and the Monte Carlo based median ranks (black mark) rarely deviate: In most cases the $5^{th} - 95^{th}$ percentile bounds overlap the original 2005 ESI rank. For about 90 countries the difference between the ESI rank and the median rank when considering alternative approaches/assumptions is less than 10 positions.

This outcome reinforces the conclusion that the ESI is a fairly robust index. The main source of the variation is the combined effect of imputation and aggregation level. For countries in the first group, the average rank deviation is 7 positions, which increases to 12 positions for the second group and 11 for the third group. Surprisingly, both OECD and non-OECD countries have an average shift in rank of almost 9 positions. These findings indicate that the number of imputations for each country is less important than the imputation model itself.

Five countries have above average differences between the ESI rank and the simulationbased median rank: Mali, Nicaragua, Mongolia, Guinea-Bissau and Syria. The 2005 ESI rank for the first four countries is almost 35 positions higher when compared to their median rank, while the opposite is valid for Syria.

Figure A.1: 2005 ESI Rank v. Median Rank

Note: Grey marks correspond to actual ESI rank and black marks correspond to median rank. Whiskers show 5th and 95th percentiles (bounds) of rank distribution.

Country	2005 ESI Rank	Best Rank	Country	2005 ESI Rank	Best Rank	Country	2005 ESI Rank	Best Rank

Table A.10: 2005 ESI Ranking and Optimal Rank for Each Country under All Combinations of Uncertainty Inputs

2. What is the optimal scenario for each country?

We interpret the 5th percentile of a country's rank distribution as its best rank. We note in Table A.10 that among the first 50 countries the most pronounced improvement in the performance are observed for Congo, the Netherlands, and Japan, which all gain more than 20 positions under a different scenario in the sensitivity analysis.

Among the countries ranked between 51st and 100th in the ESI, the most pronounced improvement under a different structure would have been for Burkina Faso and Algeria (gaining more than 40 positions in the ranking). In particular, Burkina Faso owes its improvement to the imputation, while Algeria improves its rank under aggregation at the indicator level.

Among the lowest ranked 46 countries, Belgium, South Korea and Guatemala display the most pronounced improvement (more than 50 positions). For Belgium and South Korea, this is due to aggregation at the components' level, while Guatemala's rank alters due to imputation.

3. Which countries have the most volatile rankings and why?

In order to provide an estimate of the magnitude of movement in ranks under the different simulation models, we define 'volatility' as the difference between a country's best and worst rank, which are given by the 5th and the 95th percentiles of the rank distribution. The volatility for the top ten countries, with the exception of Guyana and Argentina, suggests a robust performance for those countries. Guyana's high volatility of 23 positions is mainly attributed to the high variability in the imputation – 28 variables out of the total of 76 have been imputed – and its interaction with the aggregation level. Argentina's volatility of 9 positions is entirely due to imputation, although only 5 variables have been imputed.

Table A.11 presents the 15 countries that are affected the most by the construction procedure of the index. These countries ranked between 13 and 39 and experience differences in their best and worst ranks of 50 to 80 positions.

Only Congo, Mali, Myanmar and Belarus are ranked among the top 50 in the ESI. Their volatility can be attributed mainly to the interaction effect of imputation and aggregation level, as indicated by the Sobol sensitivity indices (1993). In some simulation runs the imputed values are favorable, partly compensating for the low scores in other variables and improving the country's rank. In other runs, however, the imputed value is far below average performance, which lowers the country's position.

4. What are the largest influences on the 2005 ESI?

To answer this question, we focus on the following comparisons:

• Imputation versus no imputation

Country	Rank ESI	Range of Ranks	Country	Rank ESI	Range of Ranks
Congo	39	14 to 78	Côte d'Ivoire	88	55 to 117
Mali	41	25 to 84	Czech Rep.	92	63 to 115
Myanmar	46	28 to 80	Algeria	96	57 to 125
Belarus	47	34 to 87	Burkina Faso	97	45 to 119
Nicaragua	66	56 to 134	Chad	104	64 to 129
Cambodia	68	35 to 105	Belgium	112	43 to 108
Guinea-Bissau	77	71 to 122	Dem. Rep. Congo	113	76 to 131
Oman	83	72 to 122			

Table A.11: Most Volatile Countries in the 2005 ESI

- Expert-weighting versus equal weighting of the 21 indicators
- Aggregation at the components level versus at the indicators level
- Non-compensatory aggregation scheme versus linear aggregation

Imputation

Imputation should be more influential for countries where missing data are a large problem. However, this relationship is not straightforward. Among the countries that miss almost 33% of their observations, only Guinea-Bissau and Myanmar are strongly affected by the imputations (Table A.12). Without imputation, Syria, Algeria, Belgium and the Dominican Republic improve their ranks between 29 and 37 positions. Conversely, Mali, Guinea-Bissau, Myanmar, and Zambia, decline 27 to 43 positions. Overall, the imputation has an average impact of 10 ranks and a rank-order correlation coefficient of 0.949.

Linear Weighting v. Budget Allocation (BA)

The ESI uses equal weights to calculate the country scores from the 21 indicators. As alternative weighting schemes we test a *"budget allocation scheme,"* in which the weights are obtained from experts with a

demonstrated understanding of environmental sustainability.

For the ESI composite indicator, the 21 experts present at the December 2004 ESI Expert Review Workshop were each given a "budget" of 100 points and asked to allocate them to the 21 indicators according to their personal judgment of the relative importance of the indicators.

Four of those experts assigned zero priority points to a significant number of indicators and were therefore eliminated from the sample. The sets of weights obtained by the 17 remaining experts together with the overall average are listed in Table A.13.

The average expert weighting is slightly different from the equal weighting used in the ESI: the indicators within the Systems and Stresses components were weighted somewhat higher than the indicators within the Human Vulnerability, Social and Institutional Capacity, and Global Stewardship. Nevertheless, the variance of experts' opinions is rather large, varying from 40-80% of the mean weight. This explains the difference between the ESI ranking and the one provided by Budget Allocation. Overall, the weighting has an average impact of 5 ranks in the simulations and a rank-order correlation coefficient of 0.989 (Table A.14).

	Imputation	ESI Rank with Imputation	Rank without Imputation	Change in Rank				
ent	Syria	117	80	-37

Table A.14: Most Improvement/Deterioration for Equal Weighting (EW) v. Budget Allocation (BA).

Because the experts weighting assigns larger weights to indicators within the Systems and Stresses Components of ESI compared to the remaining indicators, it has a positive impact on the rank of countries such as Sri Lanka and Niger, but a negative effect on others such as the Chile, South Africa or Italy.

Aggregation at the Components Level v. Aggregation at the Indicators Level

In order to further assess the robustness of the ESI, we analyze the possibility of equally weighting the five components Environmental Systems, Reducing Environmental Stresses, Human Vulnerability, Social and Institutional Capacity, and Global Stewardship, instead of the 21 indicators.

Figure A.2 compares the ranking obtained from equally weighting the 21 indicators with those obtained by equally weighting the 5 components (indicators within component receive equal weight). We find that by changing the aggregation level, the average shift of the top 40 and the bottom 30 countries of the ESI 2005 is 7 positions and the shift of the remaining countries averages 11 positions. As expected, mid-level performers display higher variability than the top and bottom of the ranking.

Weighting the five components instead of the indicators affects only 38 countries by more

than 10 positions. The average impact is 8 ranks and the rank-order correlation coefficient remains very high at 0.964.

If component weighting were used in the ESI, Belgium and South Korea would improve their ranks by almost 40 positions (Table A.15). On the contrary, countries such as Congo or Nicaragua would see their ranks decline by some 30 positions.

The reason for these substantial shifts for some countries is due to their relatively good performance in the systems and stresses components, which are more heavily weighted when the aggregation is takes place at the indicators level.

Linear Aggregation v. Non-Compensatory Multi-Criteria

The literature on index development offers a suite of aggregation techniques, including additive methods. However, additive aggregations imply certain properties and requirements for the indicators and the associated weights, which are often not desirable and at times difficult to verify. Other, less widespread, aggregation methods include multiplicative (geometric) and nonlinear aggregations such as multi-criteria analysis.

Several authors (Debreu 1960; Keeney and Raiffa 1976; Krantz, Luce et al. 1971) note

Methodology

that an additive aggregation function for a given set of indicators exists only if these indicators are mutually preferentially independent. Preferential independence is a very strong condition because it implies that the trade-off ratio between two indicators is independent of the values of the remaining indicators (Ting 1971).

In practice, this means that an additive aggregation function allows for the estimation of the marginal contribution of each indicator to the index. This marginal contribution can then be added together to yield a total value.

Average change o	ver 146 countries:			8

 Table A.15: Most Improvement/Deterioration in Ranks of Equal Weighting of Indicators (EWI) v.

 Equal Weighting of Components (EWC).

However, it is unrealistic to assume that no synergies exist among the indicators of the ESI (Funtowicz, G. et al. 1990). The combined impact of the acidifying substances SO_2 , NO_X , NH_3 and O_3 on plant growth, for example, is substantially more severe that the (linear) addition of the impacts of each of these substances alone would be (Dietz and Straaten 1992).

Furthermore, linear aggregation entails full compensability: a poor performance in some indicators can be compensated by a good performance in others. Yet not everybody would trade an increase in the 'Participation in International Collaborative Efforts' indicator with a decrease in the 'Biodiversity' indicator. Taken to its extreme, full compensability implies that weights become substitution rates (e.g., how much 'Biodiversity' can be traded against 'Participation'), and do not indicate the importance of the indicator with which they are associated.

This means that a potential inconsistency exists between the way the weights are used and their theoretical meaning. For the weights to be interpreted as "importance coefficients" (e.g. place the greatest weight on the most important "dimension"), non-compensatory aggregation procedures should be used to construct composite indices (Podinovskii 1994). This can be done using a noncompensatory multi-criteria approach

A Non-Compensatory Multi-Criteria Approach (NCMC)

A non-compensatory multi-criteria approach (NCMC) is based on mathematical aggregation conventions that can be divided into two main steps, the pair-wise comparison of countries according to the whole set of indicators used and the ranking of countries in a complete pre-order.

The result of the first step is an $(M \times M)$ matrix where M corresponds to the number of countries, commonly termed outranking matrix (Arrow and Raynaud 1986; Roy 1996). The information in the outranking matrix is used in the second step taking into consideration the intensity of preference (i.e., the difference in rank between countries for a given indicator); the number of indicators in favor of a given country; the weight attached to each indicator; and the relationship of each country with respect to all the other countries.

There are several ranking procedures for this second step (Young 1988). One possible algorithm is derived from the Condorcet-Kemeny-Young-Levenglick (CKYL) ranking procedure (Munda and Nardo 2003a). According to CKYL, the ranking of countries with the highest likelihood is the one supported by the maximum number of indicators for each pair-wise comparison, summed over all pairs of countries considered. The multicriteria method has the advantage of overcoming some of the problems inherent in additive or multiplicative aggregations: preference dependence between indicators, and the meaning of trade-offs given to the weights. Furthermore, both qualitative and quantitative information can be treated simultaneously. In addition, the approach does not require any transformation of the raw data, such as truncation, logarithmic transformation or normalization to assure the comparability of indicators.

Figure A.3 compares the results of the noncompensatory multi-criteria method with the ranking of the original ESI. In both cases we weight all 21 indicators equally. It is apparent that the aggregation method primarily affects the mid-range countries and, to a lesser extent, the laggards. Overall, the aggregation scheme has an average impact of 8 ranks and a rankorder correlation coefficient of 0.962, very similar to the impact of weighting the components instead of the indicators. In particular, while the top 50 countries move an average of only 5 positions, the next 50 countries' volatility averages 12 positions, and the lowest 46 countries shift ranks on average by 8 positions.

Both aggregation schemes, therefore, produce comparable rankings (the R^2 is 0.92). Using the NCMC, only 43 out of 146 countries display a change of more than 10 positions and none of these countries is in the top 30. When compensability among indicators is not allowed, countries performing poorly on a number of indicators decline in rank while countries with moderate values tend to improve their situation. Table A.16 shows the countries displaying the largest variation in their ranks.

3. Conclusions

We can assess the validity of the ESI rankings by evaluating how sensitive they are to the assumptions that have been made in the structure and aggregation of the indicators. Uncertainty and sensitivity analysis allows us to assess the impact of four main methodological sources of uncertainty: variability in the imputation of missing data, equal versus

Figure A.3: Linear Aggregation of Indicators v. Non-Compensatory Multi-Criteria (NCMC) Aggregation of Indicators

 Non-Compensatory Multi-Criteria (NCMC) Aggregation.

be summarized as follows: Which countries have the most volatile ranks and why? The top ten ranking countries in the ESI all have modest volatility (2 to 4 positions) with the exceptions of Guyana (23 positions) and Argentina (9 positions). This small degree of sensitivity implies a robust evaluation of performance for those countries. Guyana's high volatility is mainly attributed to imputation (28 variables out of 76 have been imputed) and its combined effect with the choice of the aggregation level. Argentina's volatility is entirely due to imputation, although only 5 variables have been imputed. The countries that present the highest volatility (between 50 and 80 positions), are found between rank 39 (Congo) and rank 113 (Dem. Rep. Congo).

aggregation scheme. The main findings can

Would the ESI be more stable if no imputation had been carried out? Imputation should be more influential for countries where missing data are a large problem. However, this relation is not straightforward. Among the countries that are missing almost 33% of the observations, only Guinea-Bissau and Myanmar are highly impacted by imputation. If no imputation were carried out, Syria, Algeria, Belgium and Dominican Republic could improve their ranks by 9 to 37 positions. Conversely, Mali, Guinea-Bissau, Myanmar and Zambia would decline in the ranking by 27 to 43 positions. Overall, imputation changes a country's rank by 10 positions on average.

What if a "non-compensatory" aggregation scheme had been used, instead of the linear aggregation scheme? Aggregation schemes matter mainly for the mid-performing countries. When the assumption of compensability among indicators is removed, countries having very poor performance in some indicators, such as Indonesia or Armenia, decline in rank, whereas countries with fewer extreme values, such as Azerbaijan or Spain, improve their position. Overall, the aggregation scheme methodology has an average impact of 8 ranks.

What if aggregation had been applied at the component level instead of at the indicator **level?** Weighting the five components equally has little effect on most countries, with a few significant exceptions. Belgium and South Korea would rise by almost 40 positions in the ranking if aggregation were done at the component level rather than the indicator level. Conversely, Congo and Nicaragua would fall by 30 positions. The reason for this effect lies in the fact that aggregation at the component level gives added weight to components with fewer indicators, such as Human Vulnerability and Global Stewardship. Overall, the level at which aggregation to the ESI takes place has an average impact of 8 ranks, similar to the impact of the aggregation scheme

What if a set of expert-derived weights had been used for the 21 indicators instead of the equal weighting? An alternate weighting obtained by surveying the experts at the December 2004 ESI Review Meeting assigns slightly higher values to indicators within the Systems and Stresses Components of ESI and less to the remaining indicators. Using these weights has a pronounced positive effect on the rank of a few countries such as Sri Lanka and Niger, but a negative effect on others such as Chile, South Africa, or Italy. Overall, the analysis shows only a small sensitivity to the weighting assumption with an average impact of 5 ranks.

1. Principal Component Analysis

Principal component analysis is a statistical method for identifying the key drivers or dimensions in a multivariate model. It is a useful tool to investigate the relationships between the 21 indicators in the ESI. This section describes in greater detail the steps and statistical assumptions underlying the method, followed by the results of applying principal component analysis to the ESI.

Principal component analysis is designed to summarize a *p*-dimensional dataset into a smaller number, q, of dimensions while preserving the variation in the data to the maximum extent possible. The objective to maximize the amount of variance explained is equivalent to losing as little of the information in the data as possible. The q new dimensions are constructed such that:

- 1. They are linear combinations of the original variables.
- 2. They are independent of each other.
- 3. Each dimension captures a successively smaller amount of the total variation in the data.

The number of linear combinations of variables can theoretically range from none to all p variables but the goal is to find the q (0 < q < p) of linear combinations of the p variables that "best" summarize the information in the data.

While principal component analysis provides considerable flexibility in determining q, the objective is to capture those features in the data that help better understand an issue of interest or to discover interesting new patterns among the relationships between variables.

The *p* original variables are combined into *q* linear combinations, which form the new principal components of the system. A standardized linear combination Z_1 of a data vector, $X_1 = (X_{11}, X_{12}, ..., X_{1p})$, of length *p* is defined as:

$$Z_1 = w_1^{t} X_1$$
, where $\sum_{i=1}^{p} w_i^{2} = 1$

Principal component analysis chooses the weights by determining the linear combination of all p variables in the transformed data set that maximizes the variance of the data. That is, the vector w of weights is calculated such that the squared difference of the new variable values and their respective means is maximized in relation to the total variance of the untransformed data.

The results for w_1 determine the first principal component. The second principal component with weights w_2 is then obtained analogously by maximizing the variance orthogonal to the direction of the first component. The third principal component with weights w_3 maximizes the residual variance in the direction orthogonal to the first and second components, and so forth.

The orthogonality of the principal components means that they are statistically independent. For example, if all water indicators of the ESI formed one principal component and all air emission indicators formed another, then any changes in either set of indicators would have no impact on the other.

The consecutive process of maximizing residual variance implies that at every step less variance is remaining. Once it falls below a specified threshold, the procedure is halted and no more additional principal components are calculated. Several criteria exist to determine the threshold value. One method considers the eigenvalues of the data matrix. The eigenvalue, λ , is the value that solves the equation

$$X_{corr}a = \lambda a$$
,

where X_{corr} is the $(p \times p)$ correlation matrix calculated from the data for *n* countries and *p* variables and *a* is a vector in $\Re^p \neq 0$.

The eigenvalues, λ_1 , ..., λ_p decrease in magnitude: $\lambda_1 > \lambda_2 > ... \lambda_p$. The first λ_j that is less then 1 corresponds to the j^{th} principal

component that explains less variance than is contained in the original, untransformed data. Values $\lambda < l$ therefore indicate that there is no gain to be expected from adding the principal component to the set of selected components. The first *(i-l)* components are sufficient to summarize the data.

Another rule of thumb for determining the number of principal components is to plot the eigenvalues in decreasing order and to connect the values in the plots by straight lines. The resulting plot is called a scree plot and usually has the form of an "elbow", starting from larger eigenvalues and dropping quickly to a lower value after which the decrease is more gradual until all p principal components are added to the system. The point where the transition from strong decrease in λ_i to λ_{i+1} to a more gradual decline occurs is often chosen for q. This "elbow" criterion generally tends to yield fewer components than the $\lambda < 1$ criterion.

A third approach using the Longman-Allen values builds on the fact that in a random multivariate normal distribution, all eigenvalues should be of approximately the same size. A random p dimensional normal data set is generated and the eigenvalues calculated. They are added to the scree plot. All eigenvalues of the original data matrix X that lie above the Longman-Allen values signify principal components that represent non-random information in the data and should therefore be retained.

In the analysis of the ESI indicator data, we use eigenvalues and the scree plot to specify the number of principal components for the 21 indicators. The resulting factor loadings of the indicators on each principal component indicate their importance, i.e., the higher the loading of an indicator, the more useful it is for explaining variation in the direction of the principal component. Variables with similarly large loadings on the same principal component can be interpreted as being related along the direction of this component. The interpretation for the ESI is that these variables measure latent concepts such as air or water quality.

As noted earlier, the loadings from principal component analysis can also be treated as inherent weights of the variables or indicators for the aggregation process. As statistically derived weights they can be compared with:

- 1. The equal weights chosen for the ESI at both the variable and the indicator level.
- 2. The preferences a panel of experts would give to the 21 indicators of the ESI.

The uncertainty and sensitivity analysis in this Appendix analyzes the differences in these approaches with respect to the resulting ESI values and ranks.

Results of the Principal Component Analysis

Our results indicate the existence of six principal components for the 21 indicators, which explain more than 76% of the variation in the data. Although the number of components selected depends to a certain extent on the decision criteria chosen to determine the cut-off point for adding more components, the scree-plot, $\lambda > I$, and explained variance criteria all support the choice of six principal components (see Table A.17 and Figure A.3 for a summary of the results).

After deciding to keep six principal components in the model, we need to repeat the model to re-allocate the indicator loadings on the selected components. For better interpretability of the results, we choose a Varimax rotation, which rotates the principal components in six-dimensional space in such a way that maximizes each indicator's loadings on only one of the six directions. After 36 iterations the rotation algorithm has converged and the rotated component matrix is shown in Table A.18.

Rotation method: Varimax with Kaiser Normalization >=0.75 >=0.5 >=0.25

From Table A.17 we already expected that most indicators would load highly on the first, second, and third principal component because they have the highest eigenvalues. Since the eigenvalues are calculated using the correlation matrix of the input data, they represent the variance explained by each principal component.

The factor loadings matrix highlights which indicators load together on the same component as well as which indicators do not load strongly on any of the six components.

The results demonstrate several important characteristics of the ESI: Firstly, the ESI is a multidimensional index and environmental sustainability is a multidimensional concept. Although the number of principal components is smaller than the number of ESI indicators, six components are required to capture at least 75% of the variation in the data. The rotated principal components also load strongly on distinct sets of indicators, which corroborates our assumption that if the ESI were based on a small number of indicators such as the Human Development Index (HDI) produced by the United Nations Development Program (UNDP), it would not fully describe all dimensions of environmental sustainability.

Secondly, the analysis of the component loadings matrix in Table A.18 above suggests that some indicators relate more closely to each other than others. These sets of indicators have high loadings on the same principal component and in the same direction along the component. Thirdly, since no indicator has low loadings on all six principal components, we can conclude that none of them is redundant in the calculation of the ESI.

Principal component 1 is determined predominantly by indicators belonging to the Social Institutional Capacity component: and Environmental Governance, Private Sector Environmental Responsiveness, Science & Technology, and Participation in Global Collaborative Efforts are the most influential indicators of this principal component. They are among the most influential indicators in the dataset, a result that confirms the findings of the correlation analysis, which also demonstrates that Environmental Governance and Participation in International Collaborative Efforts correlate most significantly with the overall ESI.

Aside from governance, principal component 1 is dominated by the indicators Natural Resource Management, Reducing Air Pollution, and Reducing Water Stress.

Other interesting findings exist for components 2 through 6. While the second component correlates strongly with several ESI indicators; most prominently with Air Quality, Eco-efficiency, and Greenhouse Gas Emissions; the remaining four components are determined by only one or two indicators. Given that all axes are orthogonal to each other, this means that the indicators loading on principal components 3 to 6 measure distinctly different aspects of environmental sustainability than are captured by components 1 and 2.

Component 3, for example, correlates most significantly with the quantity and quality of country's water resources as measures by Water Quality and Water Quantity.

Component 5, on the other hand, highlights clearly the importance of the new Vulnerability to Environment-Related Natural Disasters indicator. This indicator assesses a country's vulnerability to natural disasters that have a strong climate and weather component such as droughts, floods, and tropical cyclones. High losses of human and economic capital due to natural disasters reflect not only a natural geography-related susceptibility of the country to adverse catastrophic natural events but also a lack of capacity to prepare and deal with such events. The sixth dimension is dominated by the environmental impact countries have on other countries, as measured through the Reducing Transboundary Environmental Pressures indicator. It thereby emphasizes the importance of an indicator that is difficult to measure but vitally important to the overall sustainability picture.

The second important application of principal component analysis to the ESI consists of its ability to determine the statistical weights of the indicators. We calculate the weights of the 21 indicators as follows. Using the Varimax rotated component loading matrix, the six factor loadings of each indicator were squared to avoid negative weights and added together, thereby reflecting the total squared loadings across the six principal components. The sum of squared loadings for the 21 indicators was then re-scaled so that the final weights add up to 1. If an indicator has comparatively strong capacity to explain the variation in the data, it would be expected to receive a relatively high weight, and vice versa.

The weights estimated through principal component analysis for the 21 indicators are nearly identical, representing approximately 1/21. This finding lends further support to the choice of equal weights on the indicator level for calculating the ESI and supports the finding of the uncertainty and sensitivity analysis that budget allocation and the multi-criteria decision model do not substantially affect the ESI ranks. It should be noted, however, that weights estimated through principal component analysis reflect the average weight of each indicator, not the set of weights any particular country might apply in efforts to prioritize environmental policy.

2. Stepwise Linear Regression Analysis

Stepwise linear regression is an iterative regression method that determines the most influential variables among a set of variables. The three standard types of performing stepwise linear regression are *forward*, *backward*, and *exhaustive*. Although each method is built on the same objective of identifying the most powerful predictors in a regression model, the methods can lead to different answers.

Forward stepwise regression starts with a "zero-model" and adds one variable at a time. The variables with the highest R^2 are retained in the model and the search starts again for the next most powerful predictor, and so forth until all variables have been added. Cut-off values can be set to exclude those variables that do not add to the explanatory power of the model and to terminate the process once a desirable R^2 has been reached.

Backward stepwise regression is similar to the forward method but starts with the full model, i.e., all variables in the regression model. It then removes one variable at a time and excludes the variable that causes the smallest decrease in \mathbb{R}^2 . It then starts again removing one variable at a time, excluding the next worst predictor, and so forth until no more variables are left. Cut-off values can be set so as to avoid discarding useful variables and to prevent the model \mathbb{R}^2 falling below a desirable level.

Exhaustive stepwise regression is a combination of the two methods above in that it adds and removes variables to find the best combination of predictors. This method is computationally much more intensive, especially as the number of variables in the data set increases, but has the advantage of performing the most extensive search for the best predictors.

We apply an exhaustive stepwise regression model to determine which of the 76 ESI variables are the most useful predictors of the ESI.

For the variable model, we set the entry level of significance to 0.05, i.e., for a variable to be included in the model, it must explain at least 5% of the ESI's variance. The level of significance to remain in the model is set to 0.10 or 10% of the variance in the ESI. After 45 iterations of the procedure no more change in the model composition occurs. Based on the adjusted R^2 value statistic we select a model with 12 variables, which cumulatively explain approximately 89% of the variation in the ESI.

The selected variables and summary statistics summary are shown in Tables A.19 and A.20. Overall, Air Quality, Imports of Polluting Goods, Water Quality and Quantity, Environmental Governance, Fertility Rates, High Anthropogenic Land Conversion, and Deaths from Natural Disasters are the most important predictors for the ESI. The results thereby confirm the studies that have focused on "governance" as a critical driver of policy success (Esty and Porter 2001) but also suggest that environmental quality and stresses have important implications for the ESI scores.

It should be noted, however, that due to differential weighting of variables in the global Index, the importance of the variables as determined by statistical analysis is somewhat confounded with the magnitude of the implicit weights for each variable. Implicit weights for individual variables range from 1/42 for variables in indicators with only two variables (such as Water Quantity and Eco-Efficiency) to 1/252 for the 12 variables in the Environmental Governance indicator.

3. Cluster Analysis

Cluster analysis is a statistical technique used to separate a large group of objects into subgroups with similar characteristics. We use this technique to identify groupings of relevant peer countries.

Within each peer group, countries have a better basis for benchmarking their environmental performance because the group members are the most homogeneous with respect to their ESI indicators and the differences across the groups are maximized.

Using the ESI indicators to determine peer groups of countries for finding common benchmarks for performance evaluation is of enormous value. Cluster analysis helps to advance this process by grouping beyond level of development alone. In doing so, it enables countries to identify others who are similarly situated – thus providing a good place to start in the search for best practices.

We tested hierarchical agglomerative and divisive clustering methods as well as different distance metrics but found that Ward's method of agglomerative clustering consistently produced the best results.

A feature of agglomerative clustering is that it starts with as many individual clusters as there are countries. It then successively combines countries that are most similar to each other with respect to a quantitative similarity measure until all countries are joined in a single cluster. The similarity measure decreases during this process, while the withincluster dissimilarity increases as more and more countries are added. The trade-off lies therefore in choosing a similarity measure, or "pruning value", that yields both a relatively small number of clusters and a high level of similarity. We determine that 7 clusters yield a reasonable division between the countries.

Another clustering method, we use the k means algorithm developed by Hartigan and Wong (Hartigan and Wong (Hartigan and Wong 1979) to determine cluster membership of the countries. K means is a non-hierarchical method that requires that the number of clusters, k, be specified upfront (hence the preliminary use of Ward's method). It then iteratively finds the disjoint partition of the objects into k homogeneous groups such that the sum of squares within the clusters is minimized. The algorithm converges in fewer than 1000 iterations. The cluster membership is shown in Table A.21. Table A.22 provides additional cluster information.

 Table A.22: Additional Characteristics of Clusters

The cluster analysis reveals clear linkages between group membership and the average performance along the five ESI components. It also suggests the existence of relationships between cluster membership and additional characteristics such as average income per capita, population density, and area size.

The geographic pattern of the clusters is striking, especially since no geographical data was used in the analysis. We interpret this feature as a result of the many similarities of countries in close geographical proximity in regard to environmental conditions and pressures, economic and trade linkages, as well as with respect to social and cultural communalities.

Cluster 1 and 3 represent the developed countries with 24 of 29 OECD countries present (Luxembourg is too small to be included in the ESI). Interestingly, Taiwan is a member of cluster 1, which is characterized by high population density and industrialization combined with high social and institutional capacity. With the exception of South Korea and Taiwan, these countries share high to moderately high ESI scores. Although Taiwan is likely to be seen as an outlier in the group, its cluster membership suggests that its indicator values are more similar to this group of countries than to any of the remaining six clusters.

The differentiation between cluster 1 and 3 appears to follow characteristics captured in the distribution of ESI scores between developed and developing countries and further fine-grains the results of the analysis into the relationships between economic development and environmental sustainability. Despite comparable per capita incomes and good environmental governance, the average ESI scores for cluster 1 and 3 are markedly different (excluding the low scores of South Korea and Taiwan from cluster 1 only lifts the average ESI score by 2 points). The most prominent difference exists in the Environmental Stress component. Clearly, developed countries with large land area, low population densities – by far the lowest of all 7 clusters – and a rich natural resource base enjoy a comparative advantage because the absorptive capacity of their environments is bigger than that of smaller sized, high population density, developed countries. Although we try to correct the variables underlying the indicators for the most prevalent distortions due to size, the cluster results indicate that large area size is advantageous for environmental sustainability.

Cluster 2 is composed of the least developed countries that are characterized by weak governance and high human vulnerability. Another group of developing countries is formed by cluster 7. Cluster 2 and 7 differ in their average population size as well as their Environmental Systems and Human Vulnerability components scores. Cluster 7 includes four of the most populous countries in the world: China, India, Indonesia, and Bangladesh. Only the large geographic area of several countries in this cluster reduces their average population densities to more moderate values. This cluster's average ESI scores are only slightly higher than those of Cluster 6, which includes many of the lowest ranked countries in the ESI.

Cluster 4 includes many Eastern European countries with moderate incomes but relatively high environmental stresses, which might be a legacy of their former economic systems as well as their high average population density.

Cluster 5 comprises most of the Latin American countries, and has the second highest average ESI score and population density after Cluster 3. The good performance of the countries in this cluster has already become apparent in the high rankings of Uruguay, Guyana, Argentina, Brazil, Peru, Paraguay, and Costa Rica among the top 20 ESI countries.

Cluster 6 by contrast, has the lowest average ESI scores and is characterized by very low average scores for Social and Institutional Capacity and Global Stewardship. The countries of the Middle East and Central Asia dominate this cluster. The group is characterized by moderate environmental systems and stresses scores as well as an average human vulnerability to environmental shocks. The Social and Institutional Capacity and Global Stewardship components are the lowest across the seven clusters.

Appendix B Country Profiles

This page is intentionally blank.

Appendix B: Country Profiles

The following pages provide country profiles of ESI, component, and indicator scores for the 146 countries in the 2005 Environmental Sustainability Index.

In the upper left, part of each page, we report the subject country's Environmental Sustainability Index score and the average Index score for the countries in the subject country's peer group as defined by GDP per capita. Peer groups were assigned by dividing the countries of the index into five equal groups, sorted by GDP per capita (PPP) (Table B.1).

We use income to assign peer groups not because we wish to privilege the view that income determines environmental performance. To the contrary, one of our conclusions is that within similar levels of economic performance countries exhibit significant variation in their levels of environmental sustainability. By comparing a country's Index score with that of others in its peer group, one can get a useful measure of how effective its environmental efforts are.

In the upper right part of each page, we show a graph that provides a snapshot of a country's performance along the five components of environmental sustainability. These graphs have five axes that begin at a single point and radiate out in opposite directions. A country's score for each component is marked on each axis, and then the points are connected to form a closed area.

The size of the enclosed area is a measure of its overall performance. The shape of the area reflects the particular distribution of scores across the five components. These provide a useful benchmark for comparing performance in a slightly more precise manner than the single Index score.

Both the Index score and the Component scores are presented as standard normal percentiles. These have a theoretically possible range of 0-100; the actual range is determined by the shape of the distribution of scores across all the countries. In all cases higher scores represent higher measures of environmental sustainability.

Finally, we present the scores of the 21 indicators in a set of bar graphs. The shaded bars represent the scores of the country, and the empty bars show the average scores for the peer group. These scores represent the average of the standardized z-scores of the variables that comprise the indicators. Higher numbers represent higher levels of performance; scores near the central axis are closer to the mean score for that indicator; and negative scores represent below average performance for the complete set of 146 countries included in the ESI.

2005 Environmental Sustainability Index

Benchmarking National Environmental Stewardship

Appendix C Variable Profiles and Data

This page is intentionally blank.

Appendix C: Variable Profiles and Data

This section contains complete variable descriptions along with the original data used to produce the 2005 Environmental Sustainability Index. The variables are listed thematically according to the structure of the ESI shown in Table 10 (Table C.1 shows the variables in alphabetical order by variable code). Each page contains the following:

- The variable number.
- The variable code.
- The reference year (MRYA = Most Recent Year Available for the stated range).
- The variable description.
- The units in which the variable is measured.
- The primary data source^{*}.
- The logic for including the variable in the ESI.
- The methodology used to produce the variable, including any additional processing of the data beyond that of the data providers.
- The observed mean and median values for all countries.
- The observed minimum (min) and maximum (max) values for all countries.
- The 2.5 and 97.5 percentile cut-off values. In calculating the ESI, we truncated extreme values that fell outside the ranges of these values.
- The table with the original and imputed data. Note that where data for a given variable were imputed, the estimated values are shown in brackets.

The Section on Data Quality and Coverage in Appendix A provides further information on our assessment of the quality of the ESI variables.

^{*} A complete list of all data sources, including individual country information, follows the variable profiles.

	C.1: Variable Variable	es sorted alphabetically by variable code	
Page	Code	Variable Description	Indicator Description
281	ACEXC	Acidification exceedance from anthropogenic sulfur deposition	Reducing Ecosystem Stress
309	AGENDA21	Local Agenda 21 initiatives per million people	Environmental Governance
295	AGSUB	Agricultural subsidies	Natural Resource Management
267	ANTH10	Percentage of total land area (including inland waters) having very low anthropogenic impact	Land
268	ANTH40	Percentage of total land area (including inland waters) having very high anthropogenic impact	Land
287	BODWAT	Industrial organic water pollutant (BOD) emissions per available freshwater	Reducing Water Stress
279	CARSKM	Vehicles in use per populated land area	Reducing Air Pollution
310	CIVLIB	Civil and Political Liberties	Environmental Governance
330	CO2GDP	Carbon emissions per million US dollars GDP	Greenhouse Gas Emissions
331	CO2PC	Carbon emissions per capita	Greenhouse Gas Emissions
	COALKM	Coal consumption per populated land area	Reducing Air Pollution
		Percentage of variables missing from the CGSDI "Rio to Joburg	
311	CSDMIS	Dashboard"	Environmental Governance
323	DAI	Digital Access Index	Science and Technology
301	DISCAS	Average number of deaths per million inhabitants from floods, tropical cyclones, and droughts	Reducing Environment-Related Natural Disaster Vulnerability
302	DISEXP	Environmental Hazard Exposure Index	Reducing Environment-Related Natural Disaster Vulnerability
296	DISINT	Death rate from intestinal infectious diseases	Environmental Health
297	DISRES	Child death rate from respiratory diseases	Environmental Health
317	DJSGI	Dow Jones Sustainability Group Index (DJSGI)	Private Sector Responsiveness
262	ECORISK	Percentage of country's territory in threatened ecoregions	Biodiversity
318	ECOVAL	Average Innovest EcoValue rating of firms headquarted in a country	Private Sector Responsiveness
284	EFPC	Ecological Footprint per capita	Reducing Waste & Consumption Pressures
	EIONUM	Number of memberships in environmental intergovernmental organizations	Participation in International Collaborative Efforts
315	ENEFF	Energy efficiency	Eco-Efficiency
	ENROL	Gross tertiary enrollment rate	Science and Technology
	FERTHA	Fertilizer consumption per hectare of arable land	Reducing Water Stress
	FORCERT	Percentage of total forest area that is certified for sustainable management	Natural Resource Management
280	FOREST	Annual average forest cover change rate from 1990 to 2000	Reducing Ecosystem Stress
	FUNDING	Contribution to international and bilateral funding of environmental projects and development aid	
303	GASPR	Ratio of gasoline price to world average	Environmental Governance
	GOVEFF	Government effectiveness	Environmental Governance
282	GR2050	Percentage change in projected population 2004-2050	Reducing Population Pressure
304	GRAFT	Corruption measure	Environmental Governance
274	GRDAVL	Internal groundwater availability per capita	Water Quantity
			Reducing Waste & Consumption
286	HAZWST	Generation of hazardous waste	Pressures
261	INDOOR	Indoor air pollution from solid fuel use	Air Quality
	INNOV	Innovation Index	Science and Technology
294	IRRSAL	Salinized area due to irrigation as percentage of total arable land	Natural Resource Management
319	ISO14	Number of ISO 14001 certified companies per billion dollars GDP (PPP)	Private Sector Responsiveness
312	IUCN	IUCN member organizations per million population	Environmental Governance
313	KNWLDG	Knowledge creation in environmental science, technology, and policy	Environmental Governance
308	LAW	Rule of law	Environmental Governance
266	NBI	National Biodiversity Index	Biodiversity
258	NO2	Urban population weighted NO ₂ concentration	Air Quality

Table C.1: Variables sorted alphabetically by variable code

Page	Variable Code	Variable Description	Indicator Description
276	NOXKM	Anthropogenic NO _x emissions per populated land area	Reducing Air Pollution
291	OVRFSH	Productivity overfishing	Natural Resource Management
329	PARTICIP	Participation in international environmental agreements	Participation in International Collaborative Efforts
324	PECR	Female primary education completion rate	Science and Technology
289	PESTHA	Pesticide consumption per hectare of arable land	Reducing Water Stress
333	POLEXP	Import of polluting goods and raw materials as percentage of total imports of goods and services	Reducing Transboundary Environmental Pressures
314	POLITY	Democracy measure	Environmental Governance
306	PRAREA	Percentage of total land area under protected status	Environmental Governance
265	PRTAMPH	Threatened amphibian species as percentage of known amphibian species in each country	Biodiversity
263	PRTBRD	Threatened bird species as percentage of known breeding bird species in each country	Biodiversity
264	PRTMAM	Threatened mammal species as percentage of known mammal species in each country	Biodiversity
285	RECYCLE	Waste recycling rates	Reducing Waste & Consumption Pressures
316	RENPC	Hydropower and renewable energy production as a percentage of total energy consumption	Eco-Efficiency
321	RESCARE	Participation in the Responsible Care Program of the Chemical Manufacturer's Association	Private Sector Responsiveness
326	RESEARCH	Number of researchers per million inhabitants	Science and Technology
259	SO2	Urban population weighted SO_2 concentration	Air Quality
332	SO2EXP	SO₂ Exports	Reducing Transboundary Environmental Pressures
277	SO2KM	Anthropogenic SO ₂ emissions per populated land area	Reducing Air Pollution
283	TFR	Total Fertility Rate	Reducing Population Pressure
260	TSP	Urban population weighted TSP concentration	Air Quality
298	U5MORT	Children under five mortality rate per 1,000 live births	Environmental Health
299	UND_NO	Percentage of undernourished in total population	Basic Human Sustenance
278	VOCKM	Anthropogenic VOC emissions per populated land area	Reducing Air Pollution
273	WATAVL	Freshwater availability per capita	Water Quantity
290	WATSTR	Percentage of country under severe water stress	Reducing Water Stress
300	WATSUP	Percentage of population with access to improved drinking water source	Basic Human Sustenance
307	WEFGOV	World Economic Forum Survey on environmental governance	Environmental Governance
320	WEFPRI	World Economic Forum Survey on private sector environmental innovation	Private Sector Responsiveness
293	WEFSUB	World Economic Forum Survey on subsidies	Natural Resource Management
269	WQ_DO	Dissolved oxygen concentration	Water Quality
270	WQ_EC	Electrical conductivity	Water Quality
271	WQ_PH	Phosphorus concentration	Water Quality
272	WQ_SS	Suspended solids	Water Quality

Variable #:	1	Code:	NO2	Refe	rence Year:	MRYA 1993-2004	ļ			
Description:	Urban population v	Urban population weighted NO2 concentration								
Units:	Micrograms per cu	bic meter								
Source*:	Programme (UNH)	Organisation for Economic Co-operation and Development (OECD), United Nations Human Settlement Programme (UNHABITAT), World Health Organization, European Environment Agency, and World Resources Institute, plus country data.								
Logic:	may suffer respirate and acid rain. Thro	Poor ambient air quality affects both human and ecosystem health. Humans exposed to high NO2 concentrations may suffer respiratory illness and lung damage. NO2 is also a precursor to the formation of ground-level ozone and acid rain. Through reactions of NO2 with other substances such as volatile organic compounds (VOC) in the temporary temporary temporary temporary data and the substances such as volatile organic compounds (VOC) in the temporary tempo								
Methodology:	were used from the monitoring databas	The data from all sources were normalized by city population (in thousands) in each country. The most recent data were used from the OECD, UNHABITAT, and WHO. The EEA data were drawn from the AirBase air quality monitoring database and station coverage was balanced with the need for recent data. If a country has observations from more than one data source, the most recent observation was chosen.

Variable #:	4	Code:	INDOOR	Reference Year:	2004			
Description:	Indoor air pollution fro	om solid fuel use						
Units:	Percentage of househo	lds using solid fu	els, adjusted for ventil	ation				
Source*:	World Health Organiz	ation.						
Logic:	women who cook insi	The public health community has drawn attention to the deleterious effects of indoor air pollution, especially on women who cook inside using solid fuels. High exposure to the fumes from solid fuel combustion is dangerous to human health. Solid fuel use has further consequences for deforestation and soil depletion because of dung collection.						
Methodology:	residues). The approact separating the study pu application of relative solid fuel use. Central adults and these values	Solid fuel use is defined as the household combustion of coal or biomass (such as dung, charcoal, wood, or crop residues). The approach taken in WHO guidelines is based on a binary classification scheme for exposure levels, separating the study population into those exposed to solid fuel use and those not exposed followed by the application of relative risks derived from a comprehensive review of the current epidemiological literature on solid fuel use. Central estimates were used. For China, original data was provided separately for children and adults and these values were averaged. A single value was provided and applied to both Ethiopia and Eritrea. Corrections are made for variation in prevailing ventilation practices.

Variable #:	5 Code: ECORISK Reference Year: 2004
Description:	Percentage of country's territory in threatened ecoregions
Units:	Percentage of country's territory in threatened ecoregions
Source*:	The Nature Conservancy and World Wildlife Fund.
Logic:	Species extinction is just one aspect of the threats to biodiversity. Whole biomes (plant and animal assemblages) are also at significant risk of disappearing. Habitat conversion exceeds habitat protection by a ratio of 8:1 in temperate grasslands and Mediterranean biomes, and 10:1 in more than 140 ecoregions. These regions include some of the most biologically distinctive, species rich ecosystems on earth, as well as the last home of many threatened and endangered species.
Methodology:	The authors identify the world's terrestrial biomes and ecoregions in which biodiversity and ecological function is at greatest risk because of extensive habitat conversion and limited habitat protection. Threatened ecoregions are ecoregions with high ratios of habitat conversion to habit protection that are classified as vulnerable, endangered, or critical. This yields the land area of terrestrial ecosystems that is threatened, and the percent land area in each country that is in a threatned ecoregion. The original data distinguished between Gaza Strip and West Bank; between Montenegro and Serbia; between Jan Mayen and Svalbard. These have been combined by normalizing the percent area of ecoregions in crisis by their land area. Furthermore, the figures for France exclude

the overseas territories of French Southern and Antarctic Lands. The figures for the United Kingdom exclude Guernsey, Jersey, and Isle of Man. The figures for the United States of America exclude Howland Island, Jarvis Island, Johnston Atoll, Midway Islands, and Wake Island.

Variable #:	6	Code:	PRTBRD	Reference Year:	MRYA 2002-2003

Description: Threatened bird species as percentage of known breeding bird species in each country

Units: Threatened bird species as percentage of known breeding bird species in each country

Source*: IUCN-The World Conservation Union Species Survival Commission.

Logic: The percent of breeding birds threatened gives an estimate of a country's success at preserving its biodiversity.

Methodology: The number of bird species threatened divided by known breeding bird species in the country, expressed as a percent. Threatened species include those that are listed as "Critically Endangered, Endangered, or Vulnerable," but excludes sub-species, introduced species, species whose status is insufficiently known (categorized by the World Conservation Union or IUCN as "data deficient"), those known to be extinct, and those for which status has not been assessed (categorized by IUCN as "not evaluated"). The number of species that are globally listed as Critically Endangered are known to occur in the country but do not imply that the species are threatened within the country itself.

Variable #:	7	Code:	PRTMAM	Reference Year:	MRYA 2002-2003					
Description:	Threatened mammal sp	Threatened mammal species as percentage of known mammal species in each country								
Units:	Threatened mammal species as percentage of known mammal species in each country									

Source*: IUCN-The World Conservation Union Species Survival Commission.

Logic:

The percent of mammals threatened gives an estimate of a country's success at preserving its biodiversity.

The number of mammal species threatened was divided by known mammal species in the country, and expressed as Methodology: a percent. Mammals threatened were normalized by mammals known in each country. Mammals species and number threatened includes all species of mammals that are recorded as threatened and that are known to occur in a given country. Threatened species include those that are listed as "Critically Endangered, Endangered, or Vulnerable," but excludes sub-species, introduced species, species whose status is insufficiently known (categorized by the World Conservation Union or IUCN as "data deficient"), those known to be extinct, and those for which status has not been assessed (categorized by IUCN as "not evaluated"). Number of mammal species refers to the total number of mammal species identified and documented in a particular country or region, but excludes data on cetaceans. Total numbers include both endemic and non-endemic species. The total number of known species may include introduced species. The exclusion of cetaceans may therefore lead to overestimation for coastal countries with threatened whale and porpoise populations. The number of species that are globally listed as Critically Endangered are known to occur in the country but do not imply that the species are threatened within the country itself.

threaten	ed within	the country itself.

Description:	Freshwater avail	ability per ca	pita				(long term uterage)			
Units:	Thousand cubic	meters per pe	erson							
Source*:	Center for Envir	onmental Sys	stem Research,	Kassel Univ	versity.					
Logic:						rtant indica	tor of environmental			
Mothodology	services and the	• •				anawahla y	vatar par capita (avaraga			
Methodology:	annual surface ri evaporation from from the WaterC Kassel Universi of water availabl accurately captu hydrological dat published elsewl	The total per capita water availability was measured as the sum of internal renewable water per capita (average annual surface runoff and groundwater recharge generated from endogenous precipitation, taking into account evaporation from lakes and wetlands) and per capita water inflow from other countries. These data were derived from the WaterGap 2.1 gridded hydrological model developed by the Center for Environmental Systems Research, Kassel University, Germany. A special run of the model was performed in order to derive country-level estimates of water availability in a country. It should be noted that that the size of the grid cells (0.5 x 0.5 degree) does not accurately capture small countries. However, the fact that the model itself is based on over 30 years of global hydrological data means that the data are more comparable than similar country water resources estimates published elsewhere.

Variable #:	19	Code:	NOXKM	Reference Year:	MRYA 1990-2003						
Description:	Anthropogenic NO	Anthropogenic NOx emissions per populated land area									
Units:	Metric tons NOx en	Metric tons NOx emissions per populated land area (at 5 or more persons per square km)									
Source*:	and Development (United Nations Framework Convention on Climate Change (UNFCCC), Organization for Economic Cooperation and Development (OECD), and Intergovernmental Panel on Climate Change (IPCC), plus country data.									
Logic:	NOx emissions cor	tribute to changes	in ambient air quality	y and consequently impact hum	nan and ecosystem						
Methodology:	The data were merged as follows: UNFCCC data were available in Gigagrams for 1990, 1994, and 2000. The most recent year available was used for each country. The OECD data were available in thousand tonnes for 1980, 1985-2000 and the most recent year 1998-2000 was extracted. The OECD data were then used to fill gaps in the UNFCCC data. The resulting data set was transformed to metric tons per populated land area (km2).

Variable #:	25	Code:	GR2050	Refe	ence Year	2004		
Description:	Percentage change	e in projected popula	ation 2004-2050					
Units:	Percentage change	e in projected popula	ation 2004-2050					
Source*:	Population Referen	nce Bureau (PRB).						
Logic:	population change conditions. Project	ne projected change in population between 2004 and 2050 provides an indication of the trajectory of pulation change, which has an impact on a country's per capita natural resource availability and environmental ponditions. Projections can be made with a fair degree of accuracy because of the influence of a country's current e structure and fertility on likely future growth.						
Methodology:	The projected pop population betwee		divided by the pop	pulation in 2004 to	calculate a	percentage change in th	e

Variable #:	29	Code:	HAZWST	Reference Year:	MRYA 1992-2001				
Description: Units:	Generation of hazardo Metric tons of hazardo		managed in the country	,					
Source*:	United Nations Enviro	United Nations Environment Program, plus country data.							
Logic:	Most countries in the world are confronting real difficulties in safely disposing of their hazardous wastes. The more hazardous waste generated, the less likely that a long-term sustainable solution can be found for their proper disposal.								

Methodology: The data from the Basel Convention on the amounts of hazardous waste to be managed in the country (thousand tonnes) have been extended by OECD data for the following countries: USA, Japan, and New Zealand. The methodologies underlying both data sources may not be fully comparable although both source refer to "amounts to be managed in the country" (a comparison of OECD data and Basel Convention data for countries reporting to both sources indicates that substantial differences can exist). The objective lies therefore in increasing geographical coverage rather than complete comparability of the data. All Basel data refer to the year 2000, the additional 5 OECD values refer to years between 1992 and 1999. Also note a potential rounding bias due to the fact that the OECD data are reported in thousand metric tons while the Basel data are in metric tons.

Variable #:	30 Code: BODWAT	Reference Year:	BOD: MRYA 1990-2000; Population: 1995								
	Freshwater availability: long-term average 1961-1995										
Description:	Industrial organic water pollutant	(BOD) emissions per av	ailable freshwater								
Units:	Metric tons of daily BOD emissions per cubic km of available freshwater										
Source*:	World Bank, plus country data.										
Logic:	eutrophication of water bodies. Gi	iven these considerations	legrade water quality by contributing to the s, the biochemical oxygen demand (BOD) emissions (internal water availability + inflows from other countries).								

Methodology: Emissions of organic water pollutants were measured by biochemical oxygen demand, which is the amount of oxygen that bacteria in the water will consume in breaking down waste. This is a standard water-treatment test for the presence of organic pollutants. The data from the World Bank, which represent daily BOD emissions in kilograms, were normalized by water availability from the WaterGap version 2.1B model (Kassel University).

Variable #:	31 Code:	FERTHA R e	ference Year:	MRYA 2001-2003					
Description:	Fertilizer consumption per hectare of arable land								
Units:	100 grams fertilizer per hectare of arable land								
Source*:	World Bank, plus country data.								
Logic:	Excessive use of fertilizers from agr and levels of nutrients and leading to		0 1	n soil and water, altering chemistry					
Methodology:	Fertilizer consumption (100 grams p unit of arable land. Fertilizer produc	ts cover nitrogenous, po	tash, and phospha	te fertilizers (including ground					

rock phosphate). The time reference for fertilizer consumption is the crop year (July through June). Arable land includes land defined by the FAO as land under temporary crops (double-cropped areas are counted once), temporary meadows for mowing or for pasture, land under market or kitchen gardens, and land temporarily fallow. Land abandoned as a result of shifting cultivation is excluded. Original source: Food and Agriculture Organization, Production Yearbook and data files.

Variable #:	32	Code:	PESTHA	Reference Year:	MRYA 1990-2003						
Description: Units:	1	Pesticide consumption per hectare of arable land Kilograms pesticide consumption per hectares of arable land									
Source*:		ε	Organization (FAO),	1 5							
Logic:	Excessive use of pes	ticides in agricult	tural activities has neg	ative impacts on soil, water, h	umans and wildlife.						
Methodology:	calculate this figure, permanent cropland. organized into eight	total pesticide co Pesticide consun categories, the su	nsumption in agricult nption is measured in Im of which is used to	I per hectare of arable and per ure is divided by the total area metric tons of active ingredier determine total pesticide consider and bostericides seed the	n of arable and nts. Pesticides are sumption. The eight						

categories are: insecticides, mineral oils, herbicides, fungicides and bactericides, seed treatment - fungicides, seed treatment - insecticides, plant growth regulators and rodenticides. Arable and permanent cropland is comprised of both arable and permanent land in a given country for each year. Arable land is land under temporary crops (double-cropped areas are counted only once), temporary meadows for mowing or pasture, land under market and kitchen gardens, and land temporarily fallow (less than five years). The abandoned land resulting from shifting cultivation is not included in this category. Data for "Arable land" are not meant to indicate the amount of land that is potentially cultivable. Permanent Crops is land cultivated with crops that occupy the land for long periods and need not be replanted after each harvest, such as cocoa, coffee and rubber; this category includes land under flowering shrubs, fruit trees, nut trees and vines, but excludes land under trees grown for wood or timber.

Description:	Percentage of cou	ntry under severe wa	ter stress							
Units:	Percentage of nati	onal territory in whic	h water consump	tion exceeds 40 per	cent of avai	lable water				
Source*:	Center for Environ	nmental Systems Res	earch, University	of Kassel.						
Logic:	its overall water a		ble captures the p	percent of the territo	ory that is ur	eeds is as important as ader water stress, which				
Methodology:	Environmental Sy estimates of where	These data are derived from the WaterGap 2.1 gridded hydrological model developed by the Center for Environmental Systems Research, University of Kassel, Germany. The modelers derived gridcell by gridcell estimates of where water consumption exceeded 40 percent of the water available in that particular grid cell. These were then converted to land area equivalents, and the percent of the territory under severe water stress was calculated.

^{*} Full source information for this variable can be found at the end of this Appendix. Data in "[]" indicate imputed values; "..." means the data point is missing.

Variable #:	34 Code: OVRFSH Reference Year: Average for 1993-1998								
Description:	Productivity overfishing								
Units:	Score between 1 and 7 with high scores corresponding to high degrees of overfishing								
Source*:	South Pacific Applied Geoscience Commission (SOPAC).								
Logic:	Fish stocks are an important component of marine ecosystems. Overfishing puts pressure on ecosystems and threatens biodiversity.								
Methodology:	This measure is drawn from the EVI prepared by SOPAC in partnership with UNEP and other support. The indicator's cut-off values are based on the ratio of fisheries productivity to fish catch, or specifically the ratio of tonnes of carbon per square kilometer of exclusive economic zone per year to tonnes of fish catch per square kilometer of exclusive the following: $1 = (x - 2)^{2}$ millions:								

kilometer of shelf per year. The score ranges represent the following: 1=(>=3.2millions], 2=(3.2-1.2 millions], 3=(1.2 millions - 442 thousand], 4=(442-163 thousand], 5=(163-60 thousand], 6=(60-22 thousand], 7=(<=22

Variable #:	35	Code:	FORCERT	Refer	rence Year:	Certifications: 2004			
						Total forest area: 2000			
Description:	Percentage of total forest area that is certified for sustainable management								
Units:	Percentage of total forest area that is FSC or PEFC certified								
Source*:	The Forest Stewardship Council, and Pan-European Forest Certification Council.								
Logic:	This variable measure	s the extent to whi	ich a country seeks sus	tainable fore	estry practice	s.			
Methodology:	The forest area certified by either the Forest Stewardship Council (FSC) or the Pan-European Forest Certification thousand]. Council (PEFC) is divided by the year 2000 total forest area. To avoid double counting, if a country has forest areas under both programs, the maximum is selected. If no data are available for FSC or PEFC certified forest area, the value is set to 0. Also, ratios exceeding 100% are set to 100. This is the case for Croatia, Liechtenstein, Finland, and Norway.

Variable #:	38	Code:	AGSUB	Reference Year:	PSE and AMS: MRYA 1997-2001, EU15: 2001, Aricultural GDP: MRYA 1992-2001							
Description:	Agricultural subsidies	Agricultural subsidies										
Units:	Scale from 1 (lowest) to 8 (highest), with 0 being missing data											
Source*:	Organisation for Economic Co-operation and Development (OECD), World Trade Organization, and European Commission's Directorate General Agriculture.											
Logic:	Agricultural subsidies reduce environmental sustainability primarily by creating price distortions, promoting the production of input intensive crops, wasteful use of natural resource inputs, use of marginal and fragile lands, and rent-seeking behavior.											
Methodology:	data were taken from annual average exchar rates.com/d/USD/EUF WDI 2004). OECD da follows: The total PSF countries (John Finn, Final data were classif	and rent-seeking behavior. OECD data for producer support estimates (PSE), WTO data for aggregate measure of support (AMS). For China and India the data were taken from their notifications to the WTO. WTO data were converted from national currencies to US dollars using annual average exchange rates for 1999: ECU to USD using historic weighted 12 month average (http://www.x- rates.com/d/USD/EUR/hist1999.html), all other currencies were converted using annual average exchange rates (World Bank WDI 2004). OECD data for the EU15 refer to total PSE for the 15 members. A breakdown by member state was calculated as follows: The total PSE for EU15 was multiplied by each country's fraction of total EU15 agricultural production. OECD countries (John Finn, WTO) provided updated PSE data as percentage of total agricultural GDP replaced older OECD data. Final data were classified into 8 groups as follows: [0-10%)=1; [10-20%)=2; [20-30%)=3, [30-40%)=4, [40-50%)=5, [50- 60%)=6, [60-70%)=7,]>70%)=8. All other countries with no information are classified as 0.

Variable #:	39	Code:	DISINT	Reference Year:	MRYA 1995-2002			
Description: Units:	Death rate from intest Deaths per 100,000 pc		liseases					
Source*:	World Health Organiz	World Health Organization (WHO).						
Logic:	Indicator of the degree to environmental con-	1	opulation is affected	by poor sanitation and water q	uality, which are related			

Methodology: Standardized, age-specific death rate from intestinal infectious diseases. Results calculated as follows: For ICD-9, the codes extracted are B01 and CH01 (which cover B01-B07 in ICD-9) for Armenia, Belarus, Kazakhstan, Kyrgyzstan, Latvia, Lithuania, the Russian Federation, Tajikistan, Turkmenistan, Ukraine, Uzbekistan, and the former USSR (for some years), and C004-C006 for China (which cover 001-005, 008, and 009 in the detailed ICD-9). For ICD-10 the codes extracted are A00, A03-A09, and A010. The data were extracted by age group and aggregated by sex. They were then combined with annual population data by age group prepared by CIESIN for the year 2000. The data were then standardized for differences in the national age distributions using Canada's population structure in 2000 as it offers a relatively stable and suitable reference distribution.

Variable #:	44	Code:	DISCAS	Refere	ence Year:	1980-2000					
Description: Units:	e	Average number of deaths per million inhabitants from floods, tropical cyclones, and droughts Average number of deaths per million inhabitants									
Source*:	United Nations De	velopment Program	me (UNDP) Bure	au for Crisis Preven	tion and Reco	overy.					
Logic:	sensitivity to such hazard impacts. B	ulnerability to natural disasters is a function of the exposure to hazards (how often and how severe they are), the ensitivity to such hazards (how big the linkages are to social systems), and the resilience within a society to azard impacts. By averaging deaths from environmentally-related natural disasters, this measure provides a seful summary of overall human vulnerability to environmental change.									
Methodology:	1	The UNDP compiled these measures by aggregating and normalizing information from the OFDA/CRED nternational Disasters Data Base, Center for Research on the Epidemiology of Disasters.

ŭ	landslides, drough classified into deg exposure were flag 0-4. The resulting person was assign calculated the sum	alculate the environmental hazard exposure index, data from Dilley et al. were used. Data on exposure to slides, droughts, cyclones and floods were put into a consistent GIS database. The world's land area was ified into degrees of exposure to these four hazards. Those grid cells falling into the highest three deciles of sure were flagged. The number of high-exposure hazards was summed for each grid cell. The values range from The resulting gridded data set was then overlaid with a gridded population data set for the year 2000. Each on was assigned a score equal to the number of high-exposure hazards identified in that grid cell. We lated the sum of personal exposure scores, and divided by the total population, by country. The retically possible range was 0-4. The actual index ranged from 0 to 2.04.

Description:Percentage of variables missing from the CGSDI "Rio to Joburg Dashboard"Units:Percentage of variables missingSource*:Consultative Group on Sustainable Development Indicators (CGSDI).Logic:The greater the number of missing variables, the poorer the data availability in that country. Environmental monitoring and data systems are vital for tracking progress towards environmental sustainability.Methodology:The CGSDI (Consultative Group on Sustainable Development Indicators (progress of variables in the 10 years since the Rio Summit. The percentage of variables in the list of the CGSDI for which data are available for each country is calculated. Indicators roulded: Population, CO2 Fuel emissions, Other GHG, Urban air pollution (TSP), Arable and permanent crop Land area, Fertilizer consumption, Use of pesticides, Forest area, Population in coastal area, Withdrawal of ground and surface water, BOD in water bodies, Protected areas, Population living below poverty line (1pps/day), Gini coefficient, Unemployment total, Fernel/Male manufacturing wages, Prevalence of child manutrition, Child mortality rate, Life expectancy at birth, Access to adequate sanitation, Access to safe water, WHO Index of overall health system attainment, Immunization, DPT or measles, Contraceptive prevalence, Persistence to Grade 5, Total adult literacy rate, Floor area in main city, Number of homicides, Population growth rate, percent population in urban areas, Income per capita, Investment, Current account balance, Value of external debt present, Aid given or received, Intensity of metals & minerals use, Commercial energy use, Renewable energy resources, Energy intensity of GDP, Municipal waste generated, Hazardous waste generated, Waste recycling paper or glass, Internet hosts, Telephone mainlines, Research and evelopment expenditure. Not each contruiter is a source of the set of the set of thomicides	Variable #:	54	Code:	CSDMIS	Reference Year:	2002						
 Logic: The greater the number of missing variables, the poorer the data availability in that country. Environmental monitoring and data systems are vital for tracking progress towards environmental sustainability. Methodology: The CGSDI (Consultative Group on Sustainable Development Indicators) published the "From Rio to Johannesburg" Dashboard. The index contains 60 indicators for more than 200 countries and is a tool for the assessment of the 10 years since the Rio Summit. The percentage of variables in the list of the CGSDI for which data are available for each country is calculated. Indicators evaluated: Population, CO2 Fuel emissions, Other GHG, Urban air pollution (TSP), Arable and permanent crop Land area, Fertilizer consumption, Use of pesticides, Forest area, Population in coastal area, Withdrawal of ground and surface water, BOD in water bodies, Protected areas, Population living below poverty line (1ppp\$/day), Gini coefficient, Unemployment total, Female/Male manufacturing wages, Prevalence of child malnutrition, Child mortality rate, Life expectancy at birth, Access to adequate sanitation, Access to safe water, WHO Index of overall health system attainment, Immunization, DPT or measles, Contraceptive prevalence, Persistence to Grade 5, Total adult literacy rate, Floor area in main city, Number of homicides, Population growth rate, percent population in urban areas, Income per capita, Investment, Current account balance, Value of external debt present, Aid given or received, Intensity of metals & minerals use, Commercial energy use, Renewable energy resources, Energy intensity of GDP, Municipal waste generated, Hazardous waste generated, Nuclear waste generated, Waste recycling paper or glass, Internet hosts, Telephone mainlines, Research and development expenditure. Not calculated for Taiwan. 	-											
 monitoring and data systems are vital for tracking progress towards environmental sustainability. Methodology: The CGSDI (Consultative Group on Sustainable Development Indicators) published the "From Rio to Johannesburg" Dashboard. The index contains 60 indicators for more than 200 countries and is a tool for the assessment of the 10 years since the Rio Summit. The percentage of variables in the list of the CGSDI for which data are available for each country is calculated. Indicators evaluated: Population, CO2 Fuel emissions, Other GHG, Urban air pollution (TSP), Arable and permanent crop Land area, Fertilizer consumption, Use of pesticides, Forest area, Population in coastal area, Withdrawal of ground and surface water, BOD in water bodies, Protected areas, Population living below poverty line (1ppp\$/day), Gini coefficient, Unemployment total, Female/Male manufacturing wages, Prevalence of child malnutrition, Child mortality rate, Life expectancy at birth, Access to adequate sanitation, Access to safe water, WHO Index of overall health system attainment, Immunization, DPT or measles, Contraceptive prevalence, Persistence to Grade 5, Total adult literacy rate, Floor area in main city, Number of homicides, Population growth rate, percent population in urban areas, Income per capita, Investment, Current account balance, Value of external debt present, Aid given or received, Intensity of metals & minerals use, Commercial energy use, Renewable energy resources, Energy intensity of GDP, Municipal waste generated, Hazardous waste generated, Nuclear waste generated, Waste recycling paper or glass, Internet hosts, Telephone mainlines, Research and development expenditure. Not calculated for Taiwan. 	Source*:	Consultative Group on S	ustainable Deve	elopment Indicators (CGS	SDI).

Variable #: Description:	57 Democracy measu	Code:		POLITY	1	Reference Y	Year: Average of 199	93-2002 Polity			
Units:	5	Frend-adjusted 10-year average score with high values corresponding to high levels of democratic institutions									
Source*:	Dalita IV/ Daaiaat	TT	- f. Mamalan d	-		-					
	Polity IV Project,		•	4 11	11 14 7		. 1				
Logic:	debated, that alter an open manner.	The presence of democratic institutions increases the likelihood that important environmental issues will be ebated, that alternative views will be aired, and that decision-making and implementation will be carried out in n open manner. These factors improve the quality of environmental governance.									
Methodology:	Average of the Polity IV scores for 10 years 1993-2002 adjusted for trend: if the trend was positive, the average was increased by 1, if the trend was negative, the average was reduced by 1. The purpose of the adjustment was to reward improvement.

^{*} Full source information for this variable can be found at the end of this Appendix. Data in "[]" indicate imputed values; ".." means the data point is missing.

Nescription: Hydropower and renewable energy production as a percentage of total energy consumption Store %: USErzy Informative supercentage of total energy consumption Store %: USErzy Informative supercentage of total energy consumption Store %: USErzy Informative supercentage of total energy consumption Methode Display to the supercentage of total energy consumption USE supercentage of total energy consumption Methode Display total and use of total energy consumption USE supercentage of total energy consumption Methode Display total and use of total energy consumption Mass of total energy consumption Supercentage of total energy consumption Methode Display total energy consumption Mass of total energy consumption Mass of total energy consumption Mass of total energy consumption Algeria Display total energy consumption Mass of total energy consumption Algeria Display total energy consumption Executive total energy consumption Mass of total energy consumption Supercentage of total energy consumption Algeria Display total energy consumption Executive total energy consuption Mass of total energy consumption	Variable #:	59	Code:	RENPC	Refer	ence Year:	MRYA 2002-20	03	
Units: Hydropower and renewable energy production as a percentage of total energy consumption Source*: US Energy Information Agency. Logic: The higher the proportion of hydroelectric and other renewable energy sources, the less reliance on more environmentally damaging sources such as fossil fiel and nuclear energy. Methodology: Hydroelectric, biomass, geothermal, solar and wind electric power production were eleculated as a percent of total energy consumption. Some countries exceed 100 percent because they are net exporters of renewable energy. Mean 12.84 Max 124.46 2.5 Percentile 0 Angola 8.74 El Salvador 3.13 Libya 0.00 Senegal 0.00 Angola 8.74 El Salvador 3.13 Libya 0.00 Senegal 0.00 Argentina 14.92 Estonia 0.09 Liburatia 0.79 Sourchia 1.46 Austria 2.15 France 5.95 Madagascar 19.20 Souwaita 6.21 Austria 2.16 Gabon 2.22 Matawita 8.27 South Korea 0.43 Bangladesh 1.85 Gambia 0.00 Maitria 1.28 Sou	Description:	Hydropower and r	renewable energy	production as a perce	entage of total ener	gy consum	otion		
Source*: US Energy Information Ageny. Logie: The higher the proportion of hydroelectric and other renewable energy sources, the less reliance on more environmentally damaging sources such as fossil fuel and nuclear energy. Methodolog: Hydroelectric, biomass, geochermal, solar and wind electric power production were calculated as a percent of total energy consumption. Some countries exceed 100 percent because they are net exporters of renewable energy. ^{*} Full source information for this variable can be found at the end of this Appendix. Data in "[]" indicate imputed values; ".." means the data point is missing.

Variable #:	60	Code:	DJSGI	Refe	rence Year:	2004-2005		
Description:	Dow Jones Sustainability Group Index (DJSGI)							
- Units:	Ratio of the marke	et capitalization	n of the firms included	in the 2005 Dow Jo	ones Sustaina	bility Index to the market		
	capitalization of the firms eligible for inclusion in the Dow Jones Sustainability Index							
Source*:	Dow Jones SAM Sustainability Group.							
Logic:	terms of sustainab Sustainability Gro	The Dow Jones Sustainability Group Index tracks a group of companies that have been rated as the top 10% in terms of sustainability. Firms that are already in the Dow Jones Global Index are eligible to enter the Sustainability Group Index. Countries in which a higher percentage of eligible firms meet the requirements have a private sector that is contributing more strongly to environmental sustainability.						
Methodology:	Sustainability Inde	This variable measures the ratio of the market capitalization of the firms included in the 2005 Dow Jones Sustainability Index (World) and the market capitalization of the firms eligible for inclusion in the Dow Jones Sustainability Index (World). Market capitalization is as of 30 July 2004.

Variable #:	61	Code:	ECOVAL	Reference Year:	2004				
Description:	Average Innovest	EcoValue rating of	firms headquarted in a	country					
Units:	Average weighted score of EcoValue rating weighted by market capitalization share (values > 0 mean better environmental performance relative to peer countries, values < 0 mean poorer environmental performance)								
Source*:	Innovest Strategic	Innovest Strategic Value Advisors.							
Logic:				performance at the firm level tributing more strongly to env					
Methodology:				vest's BBB). Then the weight wers the neutral weight. A rel					

for all rated companies in a given country either raises or lowers the neutral weight. A relevance factor, based on EV21 coverage in a given country, determines the allowed deviation from neutral. Having a country score greater than zero means that, on average, companies in a given country have better environmental performance relative to their global peer group. Within each country, EcoValue levels were weighted by market capitalization share and then averaged to get a value for the individual country, based on the location of company headquarters.

Variable #:	62	Code: ISO14	Reference Year:	ISO14001: 2003, GDP: MRYA 1998-2002
Description:	Number of ISC	0 14001 certified companies per bi	llion dollars GDP (PPP)	
Units:	Number of ISC	0 14001 certified companies per bi	llion GDP in US dollars (PPP)
G*-	Dainhand Daala		. C	

Source*: Reinhard Peglau, Federal Environmental Agency, Germany.

Logic: ISO 14001 specifies standards for environmental management. The more firms that receive ISO 14001 certification, the more likely it is that industries are instituting management practices that reduce waste and resource consumption.

Methodology: Number of ISO 14001 certified companies divided by their GDP in billion US dollars (PPP).

Variable #:	67	Code:	PECR	Reference Year:	MRYA 1998-2003							
Description:	Female primary educa	tion completion 1	rate									
Units:	Female primary educa	Female primary education completion rate as percentage of females in the relevant age group										
Source*:	United Nations Educa	United Nations Educational, Scientific and Cultural Organization (UNESCO), plus country data.										
Logic:	with the overall level of	Female education is widely seen as an important factor for social and economic development. It also correlates with the overall level of schooling of a country and hence with the environmental and technological awareness, reduced incidences of water-borne diseases, and increased participation in decision-making at the household level.										
Methodology:	It is calculated as the t expressed as a percent Institute for Statistics) results are published th Completion rates exce	The proxy indicator for the primary completion rate is the gross intake rate at the last grade of primary education. It is calculated as the total number of new entrants in the last grade of primary education, regardless of age, expressed as a percentage of the population of the theoretical entrance age to the last grade (Source: UNESCO Institute for Statistics). Survival rates may at times exceed 100 due to fluctuations in enrolment. Where such results are published they should be interpreted as the country having a survival rate approaching 100%. Completion rates exceeding 100% are set to 100% so as not to give countries with greater than 100% PECR an advantage over countries with real or close to 100% PECR.

Variable #:	73	Code:	CO2GDP	Reference Year:	2000	
Description:	Carbon emissions pe	r million US dolla	rs GDP			
Units:	Metric tons of carbo	Metric tons of carbon emissions per million GDP in constant 1995 US dollars				
Source*:	ource*: Carbon Dioxide Information Analysis Center (CDIAC), plus country data.					
Logic:	Emissions of carbon dioxide are not immediately harmful to any given country but contribute to global climate change. Every country emits carbon dioxide. However, the amount of emissions per unit economic activity varies widely, with some countries being far more efficient than others.					
Methodology:	thodology: Total annual CO2 emissions in metric tons have been normalized by million GDP in constant 1995 US dollars for each country. For the People's Republic of Korea, World Bank data were not available and GDP at market prices, so current prices, US\$ (UN estimates) for 2000 were used instead.

Complete Source Information for 2005 ESI

Variable #: 1 Code: NO2

Description: Urban population weighted NO2 concentration

For ambient air pollutant concentrations: Organisation for Economic Co-operation and Development (OECD), Environmental Data Compendium 2002, http://www.oecd.org/document/21/0,2340,en_2649_37465_2516565_1_1_1_37465,00.html (accessed October 2004); United Nations Human Settlement Programme (UNHABITAT), Global Urban Observatory, Citibase, 1999, http://www.unchs.org/programmes/guo/guo_databases.asp (accessed July 2004); World Health Organization (WHO), Air Monitoring Information System 2.0, 1998; European Environment Agency, AirBase, July 2004, http://air-climate.eionet.eu.int/databases (accessed July 2004); World Resources Institute, World Resources 1998-99, Data Table 8.5;

For city population: OECD Environmental Data Compendium 2002, http://www.oecd.org/document/21/0,2340,en_2649_37465_2516565-_1_1_1_37465,00.html (accessed October 2004); Center for International Earth Science Information Network (CIESIN), alpha version of the Europe City Population database (version of August 2004).

Additional and updated data as follows: Canada: Air quality data: National Air Pollution Surveillance (NAPS) Network, Annual Data Summary for 2002, http://www.etc-cte.ec.gc.ca/publications/naps/naps2002_annual.pdf, Population data: Statistics Canada, http://www.statcan.ca/english/Pgdb/demo05a.htm. Finland: Finnish Meteorological Institute, 2004. Slovak Republic: NO2 data: Slovak Hydrometeorolotical Institute, Ministry of Environment of the Slovak Republic, "Air pollution in the Slovak Republic in 2001", Bratislava 2003 (http://oko.shmu.sk/rocenky/SHMU_Air_pollution_in_the_SR_2001.pdf), to be published by Statistical Office of the Slovak Republic in "Statistical Yearbook of the Slovak Republic, Demography and Social Statistics Section. Taiwan: Environmental Protection Agency, Taiwan, Air Quality Query Website, http://edb.epa.gov.tw/EnvStatistics/AirQlt/airpoll/-Air_pollution_tb3_1.asp. United Arab Emirates: Federal Environment Agency 2004, Environmental Annual Reports collected by respective municipalities.

Variable #: 2 Code: SO2

Description: Urban population weighted SO2 concentration

For ambient air pollutant concentrations: Organisation for Economic Co-operation and Development (OECD), Environmental Data Compendium 2002, http://www.oecd.org/document/21/0,2340,en_2649_37465_2516565_1_1_1_37465,00.html (accessed October 2004); United Nations Human Settlement Programme (UNHABITAT), Global Urban Observatory, Citibase, 1999, http://www.unchs.org/programmes/guo/guo_databases.asp (accessed July 2004); World Health Organization (WHO), Air Monitoring Information System 2.0, 1998; European Environment Agency, AirBase, July 2004, http://air-climate.eionet.eu.int/databases (accessed July 2004); World Resources Institute, World Resources 1998-99, Data Table 8.5.

For city population: OECD Environmental Data Compendium 2002, http://www.oecd.org/document/21/0,2340,en_2649_37465_2516565-_1_1_1_37465,00.html (accessed October 2004); Center for International Earth Science Information Network (CIESIN), alpha version of the Europe City Population database (version of August 2004).

Additional and updated country data as follows: Belgium: Interregional Cell for the Environment (IRCEL), Frans Fierens, and Walloon State of the Environment Cell - Directorate-General for Natural Resources and the Environment (CEEW - DGRNE), Vincent Brahy. http://statbel.fgov.be. Canada: SO2 data, National Air Pollution Surveillance (NAPS) Network, Annual Data Summary for 2002, http://www.etc-cte.ec.gc.ca/publications/naps/naps/2002_annual.pdf. City population data, http://www.statcan.ca/english/Pgdb/demo05a.htm. Taiwan: SO2 data, Environmental Protection Administration (EPA), Taiwan, http://edb.epa.gov.tw/EnvStatistics/AirQlt/airpoll/index.asp, http://www.dgbas.gov.tw/dgbas03/bs8/look/looky.htm. City population data, Directorate General of Budget Accounting and Statistics, The Third Bureau, Socio-Economic Data of Taiwan. Turkey: SO2 data, Ministry of Health, http://www.die.gov.tr/ENGLISH/SONIST/CEVRE/e05052004.html. City population data, State Institute of Statistics., General Population Census 2000. United Arab Emirates: Federal Environment Agency, Environmental Annual Reports collected in respective municipalities.

Variable #: 3 Code: TSP

Description: Urban population weighted TSP concentration

<u>For ambient air pollutant concentrations:</u> Organisation for Economic Co-operation and Development (OECD), Environmental Data Compendium 2002, http://www.oecd.org/document/21/0,2340,en_2649_37465_2516565_1_1_1_37465,00.html (accessed October 2004); United Nations Human Settlement Programme (UNHABITAT), Global Urban Observatory, Citibase, 1999, http://www.unchs.org/programmes/guo/guo_databases.asp (accessed July 2004); World Health Organization (WHO), Air Monitoring Information System 2.0, 1998; European Environment Agency, AirBase, July 2004, http://air-climate.eionet.eu.int/databases (accessed July 2004); World Resources Institute, World Resources 1998-99, Data Table 8.5.

For city population: OECD Environmental Data Compendium 2002, http://www.oecd.org/document/21/0,2340,en_2649_37465_2516565-_1_1_1_37465,00.html (accessed October 2004); Center for International Earth Science Information Network (CIESIN), alpha version of the Europe City Population database (version of August 2004).

Additional and updated country data as follows: Albania: Ministry of Environment Canada: PM10 data: National Air Pollution Surveillance (NAPS) Network, Annual Data Summary for 2002, http://www.etc-cte.ec.gc.ca/publications/naps/naps2002_annual.pdf, City population data: http://www.statcan.ca/english/Pgdb/demo05a.htm. Costa Rica: TSP data: Universidad Nacional, Heredia, CostaRica, Laboratorio de Contaminantes cited by Indicadores del Desarrollo Sostenible de Costa Rica 2002, Observatorio del Desarrollo (OdD), Universidad de Costa Rica, http://www.odd.ucr.ac.er. Slovak Republic: PM10 data: Slovak Hydrometeorolotical Institute, Ministry of Environment of the Slovak Republic, "Air pollution in the Slovak Republic in 2001", Bratislava 2003 (http://oko.shmu.sk/rocenky/SHMU_Air_pollution_in_the_SR_2001.pdf), to be published by Statistical Office of the Slovak Republic in "Statistical Yearbook of the Slovak Republic, 2004" and "Environment in the Slovak Republic Selected indicators in 1999 - 2003", City population data: Statistical Office of the Slovak Republic, Demography and Social Statistics Section. Taiwan: PM10 data, Air Quality QueryWebsite, EPA, Taiwan, http://edb.epa.gov.tw/EnvStatistics/AirQlt/airpoll/Air_pollution_tb3_2.asp. Directorate General of Budget Accounting and Statistics, Socio-Economic Data of Taiwan, http://www.dgbas.gov.tw/dgbas03/bs8/look/looky.htm. United Arab Emirates: Federal Environment Agency, Environmental Annual Reports collected respective municipalities. United States: Environmental Protection Agency, http://www.epa.gov/air/airtrends/aqtrnd01/pmatter.html.

Variable #: 4 Code: INDOOR

Description: Indoor air pollution from solid fuel use

World Health Organization, "Assessing the environmental burden of disease at national and local levels", by Manish A. Desai, Sumi Mehta, Kirk R. Smith, http://www.who.int/quantifying_ehimpacts/publications/9241591358/en/ (accessed December 2004).

Variable #: 5 Code: ECORISK

Description: Percentage of country's territory in threatened ecoregions

Hoekstra, Jonathan M., Timothy M. Boucher, Taylor H. Ricketts, and Carter Roberts. 2005. Confronting a biome crisis: global disparities of habitat loss and protection. Ecology Letters, 8, pp. 23-29, see also http://www.blackwellpublishing.com/abstract.asp?aid=4&iid=1&-ref=1461-023X&vid=8 (accessed January 2005).

Variable #: 6 Code: PRTBRD

Description: Threatened bird species as percentage of known breeding bird species in each country

IUCN-The World Conservation Union Red List of Threatened Species 2002 and 2003, http://www.redlist.org/info/tables.html (accessed September 2004), and World Resources Institute (WRI) 2000-2001 Earthtrends Table BI.2 Globally Threatened Species: Mammals, Birds, and Reptiles, http://earthtrends.wri.org/pdf_library/data_tables/bi2n_2000.pdf (accessed January 2005).

Additional and updated country data as follows: Taiwan: The Agricultural Council, Taiwan, Birds, Animal Division, Endemic Species Research Center, http://www.tesri.gov.tw/content/animal/ani_bird.asp, Wild Bird Federation Taiwan, The list of conserved wild animals, http://www.bird.org.tw/ebird/b/webrace/school/10/new_page_4.htm.

Variable #: 7 Code: PRTMAM

Description: Threatened mammal species as percentage of known mammal species in each country

IUCN-The World Conservation Union Red List of Threatened Species 2002 and 2003, http://www.redlist.org/info/tables.html (accessed September 2004), and World Resources Institute (WRI) 2000-2001 Earthtrends Table BI.2 Globally Threatened Species: Mammals, Birds, and Reptiles, http://earthtrends.wri.org/pdf_library/data_tables/bi2n_2000.pdf (accessed January 2005).

Additional and updated country data as follows: Taiwan: The Agricultural Council, Taiwan, Mammal, Animal Division, Endemic Species Research Center, http://www.tesri.gov.tw/content/animal/ani_mamal.asp, Endemic Species Research Center, The list of conserved wild animals, http://nature.tesri.gov.tw/tesriusr/internet/wildlist.cfm?Kind=0.

Variable #: 8 Code: PRTAMPH

Description: Threatened amphibian species as percentage of known amphibian species in each country

IUCN-The World Conservation Union Species Survival Commission, Conservation International-Center for Applied Biodiversity Science, and NatureServe. 2004, IUCN Global Amphibian Assessment, http://www.globalamphibians.org/ (accessed January 2005).

Variable #: 9 Code: NBI

Description: National Biodiversity Index

Convention on Biological Diversity, Global Biodiversity Outlook (2001, with second edition to be published in 2004), http://www.biodiv.org/doc/publications/gbo/gbo-anx-01-en.pdf (accessed January 2005).

Variable #:	10	Code:	ANTH10

Description: Percentage of total land area (including inland waters) having very low anthropogenic impact

The Human Influence Index (HII) version 2, Center for International Earth Science Information Network (CIESIN) including nine underlying public domain data sets: World Roads (US Department of Defense National Imaging and Mapping Agency (NIMA) Vector MAP (VMAP0)), World Railroads (NIMA, VMAP0), Navigable Rivers (NIMA, VMAP0-hydropoly data set), Coastlines (NIMA, coastline data), GPW3 Population Density Data (CIESIN Gridded Population of the World version 3 Population Density Grid adjusted to match UN figures), GRUMP version 1 Urban Extent Data (CIESIN Gridded Rural-Urban Mapping Project, Urban extent dataset), DMSP Nightime Stable Lights (US Department of Defense, Defense Meteorological Satellite Program), and Cropland Data (Center for Sustainability and Global Environment (SAGE), Navin Ramankutty), http://www.ciesin.columbia.edu/wild_areas/ (accessed January 2005).

Variable #: 11 Code: ANTH40

Description: Percentage of total land area (including inland waters) having very high anthropogenic impact

The Human Influence Index version 2 by the Center for International Earth Science Information Network (CIESIN) using 9 underlying public domain data sets. The underlying data sets are: World Roads (US Dept. of Defense National Imaging and Mapping Agency, NIMA, VMAP0), World Railroads (NIMA, VMAP0), Navigable Rivers (NIMA, VMAP0-hydropoly data set), Coastlines (NIMA, coastline data), GPW3 Population Density Data (CIESIN Gridded Population of the World v3 Population Density Grid adjusted to match UN figures), GRUMP v1 Urban Extent Data (CIESIN Gridded Rural Urban Mapping Project, Urban extent data), DMSP Nighttime Stable Lights (US Dept. of Defense, Defense Meteorological Satellite Program), and Cropland Data (SAGE Navin Ramankutty, Center for Sustainability and Global Environment), http://www.ciesin.columbia.edu/wild_areas/ (accessed January 2005).

Variable #: 12 Code: WQ DO

Description: Dissolved oxygen concentration

United Nations Environment Programme (UNEP), Global Environmental Monitoring System/Water Quality Monitoring System, http://www.gemswater.org/publications/index-e.html, Organisation for Economic Co-operation and Development (OECD) Environmental Data Compendium 2002, Inland Water, 3.4A, http://www.oecd.org/dataoecd/8/19/2958157.pdf (accessed June 2004), European Environment Agency (EEA) Water Base: QUALITY_LAKES_EN_V4, http://dataservice.eea.eu.int/dataservice/metadetails.asp?id=661 (accessed June 2004), QUALITY_RIVERS_EN_V4, http://dataservice.eea.eu.int/dataservice/metadetails.asp?id=660 (accessed June 2004).

Additional and updated country data as follows: Belgium: Vlaamse Milieumaatschappij - Flemish Environment Agency (VMM), Rudy Vannevel, Direction Générale des Ressources Naturelles et de l'Environnement (DGRNE), Dominique Wyllock, data sent to United Nations Environment Programme - Global Environment Monitoring System/Water Division (UNEP-GEMS/Water). Finland: Finnish Environment Institute, Common Procedures for Exchange of Information (Council Decision 77/795/EEC). Japan: Ministry of the Environment, http://www.env.go.jp/water/suiiki/index.html. Slovak Republic: Slovak Hydrometeorological Institute, to be published in "Environment in the Slovak Republic (Selected indicators in 1999 - 2003)" by Statistical Office of the Slovak Republic. Taiwan: Environmental Protection Administration, The Statistical Yearbook of EPA, http://www.epa.gov.tw/english/.

Variable #: 13 Code: WQ_EC

Description: Electrical conductivity

United Nations Environment Programme (UNEP), Global Environmental Monitoring System/Water Quality Monitoring System, http://www.gemswater.org/publications/index-e.html (accessed June 2004), European Environment Agency (EEA) Water Base: QUALITY_LAKES_EN_V4, http://dataservice.eea.eu.int/dataservice/metadetails.asp?id=661 (accessed June 2004).

Additional and updated country data as follows: Belgium: Vlaamse Milieumaatschappij - Flemish Environment Agency (VMM), Rudy Vannevel, Direction Générale des Ressources Naturelles et de l'Environnement (DGRNE), Dominique Wyllock, data sent to United Nations Environment Programme - Global Environment Monitoring System/Water Division (UNEP-GEMS/Water). Finland: Finnish Environment Institute, Common Procedures for Exchange of Information (Council Decision 77/795/EEC). Taiwan: Environmental Protection Administration, The Statistical Yearbook of EPA, http://www.epa.gov.tw/english/.

Variable #: 14 Code: WQ_PH

Description: Phosphorus concentration

United Nations Environment Programme (UNEP), Global Environmental Monitoring System/Water Quality Monitoring System, http://www.gemswater.org/publications/index-e.html (accessed June 2004), European Environment Agency (EEA) Water Base: QUALITY_LAKES_EN_V4, http://dataservice.eea.eu.int/dataservice/metadetails.asp?id=661 (accessed June 2004), European Environment Agency (EEA) Water Base: QUALITY_RIVERS_EN_V4, http://dataservice.eea.eu.int/dataservice/metadetails.asp?id=660 3 (accessed June 2004), Organisation for Economic Co-operation and Development (OECD) Environmental Data Compendium 2002, Inland Water, 3.4D, http://www.oecd.org/dataoecd/8/19/2958157.pdf (accessed April 2004).

Additional and updated country data as follows: Finland: Finnish Environment Institute, Common Procedures for Exchange of Information (Council Decision 77/795/EEC). Slovak Republic: Slovak Hydrometeorological Institute, to be published in "Environment in the Slovak Republic (Selected indicators in 1999 - 2003)" by Statistical Office of the Slovak Republic. Taiwan: Environmental Protection Administration (EPA), Reservoir Monitoring Database, http://alphapc.epa.gov.tw/get_river_fixed.html, http://alphapc.epa.gov.tw/get_dam_fixed.html. Zimbabwe: Harare City Health Department, Zimbabwe.

Variable #: 15 Code: WQ_SS

Description: Suspended solids

United Nations Environment Programme (UNEP), Global Environmental Monitoring System/Water Quality Monitoring System. http://www.gemswater.org/publications/index-e.html (accessed June 2004).

Additional and updated country data as follows: Belgium: Vlaamse Milieumaatschappij - Flemish Environment Agency (VMM), Rudy Vannevel, Direction Générale des Ressources Naturelles et de l'Environnement (DGRNE), Dominique Wyllock, data sent to United Nations Environment Programme - Global Environment Monitoring System/Water Division (UNEP-GEMS/Water). Japan: Ministry of the Environment, http://www.env.go.jp/water/suiiki/index.html. Slovak Republic: Slovak Hydrometeorological Institute, to be published in "Environment in the Slovak Republic (Selected indicators in 1999 - 2003)" by Statistical Office of the Slovak Republic. Taiwan: Environmental Protection Administration, The Statistical Yearbook of EPA, http://www.epa.gov.tw/english/.

Variable #: 16 Code: WATAVL

Description: Freshwater availability per capita

Center for Environmental System Research, Kassel University, Water GAP 2.1e, 2004 (communication)

Variable #:	17	Code:	GRDAVL

Description: Internal groundwater availability per capita

For groundwater data: Food and Agricultural Organization, United Nations, AQUASTAT database, Groundwater produced internally (cubic km/year); For population data: Population Reference Bureau, 2004 World Population Data Sheet, total mid-year population 2004, http://www.prb.org/datafind/datafinder5.htm (accessed December 2004); For the United States of America the substitute used is Internal Renewable Water Resources: Groundwater recharge, volume in cubic kilometers for the period 1977-2001 from FAO AQUASTAT (obtained through WRI EarthTrends portal at http://earthtrends.wri.org/searchable_db/index.cfm?step=countries&cID=190&theme=2-&variable_id=11&action=select_years (accessed December 2004).

Variable #: 18 Code: COALKM

Description: Coal consumption per populated land area

For coal data: United States Energy Information Agency, http://www.eia.doe.gov/emeu/international/contents.html (accessed January 2005);

For populated land area data: Center for International Earth Science Information Network (CIESIN) Gridded Population of the World version 3 (GPW).

Variable #: 19 Code: NOXKM

Description: Anthropogenic NOx emissions per populated land area

<u>For NOx emissions data:</u> United Nations Framework Convention on Climate Change (UNFCCC) Greenhouse Gas (GHG) emissions database, http://ghg.unfccc.int/default1.htf?time=10%3A43%3A50+PM (accessed April 2004), OECD Environmental Data Compendium 2002, Air and Climate, Emissions by Source, http://www.oecd.org/document/21/0,2340,en_2649_37465_2516565-_1_1_37465,00.html. (accessed October 2004), IPCC Special Report on Emissions Scenarios, Data Version 1.1 B1 Illustrative Marker Model with Model IMAGE with data for reference year 2000.

For Populated land area data: Gridded Population of the World Version 3, 2004, Center for International Earth Science Information Network (CIESIN). http://sedac.ciesin.columbia.edu/plue/gpw/index.html?main.html&2 (2004).

Additional and updated country data as follows. Austria: United Nations Economic and Social Council Economic Commission for Europe, Convention on Long-Range Transboundary Air Pollution (UNECE-CLRTAP) - Submission 2004, http://www.unece.org/env/lrtap/welcome.html. Belgium: Vlaamse Milieu Maatschappij - Flemish Environment Agency, Miet D'heer. Denmark: http://europa.eu.int/comm/eurostat/newcronos/reference/display.do?screen=welcomeref&open=/envir/milieu/air&language=en&product=EU environment energy&coot=EU environment energy&scrollto=199. Zimbabwe: Central Statistical Office, Motor Vehicle Report.

Variable #: 23 Code: FOREST

Description: Annual average forest cover change rate from 1990 to 2000

United Nations Food and Agriculture Organization (FAO) Forest resources assessment (FRA) 2000, http://www.fao.org/forestry/fo/-fra/index.jsp (accessed December 2004).

Variable #: 24 Code: ACEXC

Description: Acidification exceedance from anthropogenic sulfur deposition

Stockholm Environment Institute at York, Acidification in Developing Countries: Ecosystem Sensitivity and the Critical Loads Approach at the Global Scale, 2000, available in pdf at http://www.york.ac.uk/inst/sei/pubs/globalassess.pdf (accessed January 2005).

Variable #: 25 Code: GR2050

Description: Percentage change in projected population 2004-2050

Population Reference Bureau (PRB). 2004 World Population Data Sheet. http://www.prb.org/datafind/datafinder5.htm (accessed December 2004).

Variable #: 26 Code: TFR

Description: Total Fertility Rate

Population Reference Bureau (PRB), 2004 World Population Data Sheet, http://www.prb.org/datafind/datafinder5.htm (accessed January 2005).

Variable #: 27 Code: EFPC

Description: Ecological Footprint per capita

<u>Primary source:</u> Redefining Progress Ecological Footprint of Nations 2004, http://www.redefiningprogress.org/newpubs/index.shtml (accessed January 2005).

Additional country data as follows: Afghanistan, Niger, Somalia, Togo, Uzbekistan, Yemen: The World Wildlife Fund (WWF), Living Planet Report 2002, http://www.wwf.org.uk/filelibrary/pdf/livingplanet2002.pdf (accessed January 2005). Taiwan: Lee, Y.J. and A.C. Chen. 1998. Examining sustainable development of Taiwan in terms of ecological footprints. Review in Economic and Social Institutions, 22, pp. 437-458, published in Chinese by the Council for Economic Planning.

Variable #: 28 Code: RECYCLE

Description: Waste recycling rates

Organisation for Economic Co-operation and Development (OECD) Environmental Data Compendium 2002, http://www.oecd.org/document/21/0,2340,en_2649_37465_2516565_1_1_1_37465,00.html (accessed October 2004), and United Nations Human Settlement Programme (UNHABITAT) Global Urban Indicators Database 1998, http://www.unhabitat.org/programmes/guo/guo_indicators.asp (accessed December 2003).

Additional and updated country data as follows. Taiwan: Environmental Protection Administration (EPA), Taiwan, http://210.69.101.88/WEBSTATIS/webindex.htm.

Variable #: 29 Code: HAZWST

Description: Generation of hazardous waste

United Nations Environment Program, Secretariat of the Basel Convention for 1992-2000 data, "Global Trends in Generation and Transboundary Movements of Hazardous Wastes and Other wastes", Appendix 4, http://www.basel.int/natreporting/trends2.pdf (accessed November 2004), Secretariat of the Basel Convention, Data as Reported by Parties, http://geodata.grid.unep.ch for 2001 (accessed November 2004), Organisation for Economic Co-operation and Development (OECD) Environmental Data Compendium 2002, http://www.oecd.org/document/21/0,2340,en_2649_37465_2516565_119656_1_1_37465,00.html (accessed July 2004).

Additional and updated country data as follows: Austria: Umweltbundesamt (Federal Environment Agency),

http://www.umweltbundesamt.at. Estonia: Statistical Office of Estonia, http://pub.stat.ee/px-web.2001/I_Databas/Environment/-01Environmental_pressure/06Generation_of_waste/06Generation_of_waste.asp. United Arab Emirates: Ministry of Agriculture and Fisheries, Annual Reports 2002 and 2003.

Variable #: 33 Code: WATSTR

Description: Percentage of country under severe water stress

Center for Environmental Systems Research, University of Kassel, WaterGap 2.1, 2000 (communication).

Variable #: 34 Code: OVRFSH

Description: Productivity overfishing

South Pacific Applied Geoscience Commission (SOPAC), Environmental Vulnerability Index, Indicator 34 -- Productivity overfishing.

For Fisheries data: Food and Agriculture Organization (FAO), United Nations, 1993-1998.

For Productivity data: University of British Columbia.

Variable #: 35 Code: FORCERT

Description: Percentage of total forest area that is certified for sustainable management

For certifications: The Forest Stewardship Council, URL: http://www.fsc.org/fsc/whats_new/documents/Docs_cent/4 (accessed December 2004) for FSC certified forest area and the Pan-European Forest Certification Council, http://www.pefc.cz/register/statistics.asp (accessed December 2004);

For Total forest area: World Resources Institute for Total Forest Area, URL: http://earthtrends.wri.org/searchable_db/index.cfm?-theme=9&variable_ID=296&action=select_countries (accessed January 2005).

Variable #: 36 Code: WEFSUB

Description: World Economic Forum Survey on subsidies

World Economic Forum (WEF) Survey, The Global Competitiveness Report 2003-2004, Porter, Michael E. et al, Oxford University Press, 2003-2004, http://www.weforum.org/site/knowledgenavigator.nsf/Content/KB+Country+Profiles (accessed January 2005).

Variable #: 37 Code: IRRSAL

Description: Salinized area due to irrigation as percentage of total arable land

United Nations Food and Agricultural Organization (FAO), http://www.fao.org/ and also http://www.fao.org/documents/-show cdr.asp?url file=/DOCREP/005/Y4263E/y4263e04.htm (accessed January 2005).

Variable #: 38	3 Code:	AGSUB
----------------	---------	-------

Description: Agricultural subsidies

For producer support estimates (PSE) data: Organisation for Economic Co-operation and Development (OECD); OECD Producer Support Estimates for 2001 as a percentage of agricultural GDP and data for China and India were provided by John Finn (World Trade Organization);

For share of agricultural production of EU15 of total EU agricultural production: European Commission, Directorate General Agriculture, Agricultural Situation in the EU 2003; For currency exchange rates data: World Bank, World Development Indicators (WDI) 2004, http://www.worldbank.org/data/wdi2004/ (accessed December 2004); For conversion of ECU into USD: http://www.x-rates.com/d/USD/EUR/hist1999 (accessed December 2004).

Variable #: 39 Code: DISINT

Description: Death rate from intestinal infectious diseases

World Health Organization (WHO), Mortality databases for International Classification of Deaths (ICD) revisions 9 and 10, July 200http://www3.who.int/whosis/menu.cfm?path=mort (accessed January 2005).

Variable #: 40 Code: DISRES

Description: Child death rate from respiratory diseases

World Health Organization (WHO), Mortality databases for International Classification of Deaths (ICD) revisions 9 and 10, July 2004, http://www3.who.int/whosis/menu.cfm?path=mort (accessed January 2005).

Variable #: 41 Code: U5MORT

Description: Children under five mortality rate per 1,000 live births

United Nations Statistics Division (UNSD), Demographic Yearbook Database, primary data source: UNICEF, http://unstats.un.org/-unsd/demographic/default.htm (accessed January 2005).

Additional and updated data as follows: Australia: Australian Bureau of Statistics, Births, Australia 2002 (cat. No. 3301.0), Deaths, Australia (cat. No. 3302.0). Austria: Statistics Austria. Costa Rica: Instituto Nacional de Estadística y Censos 2004, "Estadísticas Vitales del 2003", based on CIE-10 (Clasificación Internacional de Enfermedades y Problemas Relacionados con la Salud, X revisión, volumen I, Organización Panamericana de la Salud y Organización Mundial de la Salud, http://www.inec.go.cr. Lithuania: Statistics Lithuania, Eurostat. Mauritius: Ministry of Public Utilities, Statistics Unit. New Zealand: Statistics New Zealand, http://www.stats.govt.nz/datasets/a-z-list.htm. Poland: Central Statistical Office Dissemination information, Polish Census 2002. Taiwan: Department of Health, http://www.doh.gov.tw/EN/Webpage/index.aspx, Table 10.Number of deaths classified according to the basic tabulation list of death by sex and age, Taiwan Area, 2002, Age Composition of Population, Taiwan Area, http://www.doh.gov.tw/-statistic/data/生命統計/91/02.XLS. United Arab Emirates: Ministry of Health, Annual Statistical Report, 2003 and Annual Report of Preventive Medicine. 2003.

Variable #: 42 Code: UND NO

Description: Percentage of undernourished in total population

United Nations Food and Agriculture Organization (FAO), The State of Food Insecurity in the World 2003 Report, http://www.fao.org/docrep/006/j0083e/j0083e/j0083e/00.htm (accessed January 2005).

Variable #: 43 Code: WATSUP

Description: Percentage of population with access to improved drinking water source

World Health Organization, United Nations Children's Fund, WHO/UNICEF Joint Monitoring Programme on Water Supply and Sanitation (JMP), http://www.who.int/water_sanitation_health/monitoring/jmp2004/en/ (accessed January 2005).

Additional and updated data as follows: Belgium: Institut National de Statistiques - National Institute of Statistics (INS), http://statbel.fgov.be, officially reported to Eurostat in 2003. Ireland: Central Statistics Office, Social Statistics Integration, Dublin. Italy: Istituto Nazionale di Statistica (Istat - National Institute of Statistics), "13° Censimento Generale della Popolazione, 1991". Taiwan: United Nations Statistical Division, http://unstats.un.org/unsd/mi/mi_goals.asp. United Arab Emirates: Ministry of Electricity

Variable #: 44 Code: DISCAS

Description: Average number of deaths per million inhabitants from floods, tropical cyclones, and droughts

United Nations Development Programme (UNDP) Bureau for Crisis Prevention and Recovery, A Global Report on Reducing Disaster Risk - A Challenge for Development, UNDP 2004, available at http://www.undp.org/bcpr/disred/rdr.htm (accessed January 2005).

Variable #: 45 Code: DISEXP

Description: Environmental Hazard Exposure Index

The World Bank, Natural Disaster Hotspots: A Global Risk Analysis, Maxx Dilley, Robert Chen, Uwe Deichmann, Arthur L. Lerner-Lam and Margaret Arnold with Jonathan Agwe, Piet Buys, Oddvar Kjekstad, Bradfield Lyon and Greg Yetman, 2005, Washington DC, see also http://iri.columbia.edu/impact/project/RiskHotspot/ (accessed January 2005).

Variable #: 46 Code: GASPR

Description: Ratio of gasoline price to world average

World Bank, World Development Indicators 2004, http://www.worldbank.org/data/wdi2004/.

Additional and updated country data as follows: Mauritius: Digest of Road Transport & Road Accident Statistics, 2003, Table 3.1. Taiwan: US Energy Information Administration (EIA), http://www.eia.doe.gov/emeu/international/petroleu.html#GasolinePrices.

Variable #: 47 Code: GRAFT

Description: Corruption measure

World Bank, Governance Indicators: 1996-2002, http://www.worldbank.org/wbi/governance/govdata2002/index.html (accessed December 2004).

Variable #:	48	Code:	GOVEFF
-------------	----	-------	--------

Description: Government effectiveness

World Bank, http://www.worldbank.org/wbi/governance/govdata2002/index.html (accessed January 2005).

Variable #: 49 Code: PRAREA

Description: Percentage of total land area under protected status

United Nations Environment Program - World Conservation Monitoring Centre (UNEP-WCMC), World Database on Protected Areas (WDPA) Version 6, World Database on Protected Areas Consortium, Cambridge, U.K., August, 2003, accessed through the World Resources Institute (WRI) http://earthtrends.wri.org/ (accessed December 2003).

Additional and updated country data as follows: Belgium: Royal Belgian Institute of Natural Sciences (RBINS), Marianne Schlesser, http://bch-cbd.naturalsciences.be/. Costa Rica: Sitema Nacional de Áreas Protegidas (SINAC) - Ministerio de Ambiente y Energia (MINAE), http://www.sinac.go.cr/asp/index.html. United Arab Emirates: Federal Environment Agency Ministry of Economy and Planning, "Survey of Protected Areas in United Arab Emirates".

Variable #: 50 Code: WEFGOV

Description: World Economic Forum Survey on environmental governance

World Economic Forum (WEF) Survey, The Global Competitiveness Report 2003-2004, Porter, Michael E. et al, Oxford University Press, 2003-2004, http://www.weforum.org/site/knowledgenavigator.nsf/Content/KB+Country+Profiles (accessed January 2005).

Variable #: 51 Code: LAW

Description: Rule of law

World Bank, http://www.worldbank.org/wbi/governance/govdata2002/index.html (accessed January 2005).

Variable #: 52 Code: AGENDA21

Description: Local Agenda 21 initiatives per million people

For initiatives data: International Council for Local Environmental Initiatives (ICLEI), 2001, Second Local Agenda 21 Survey, Background Paper Number 15, New York, United Nations Department of Economic and Social Affairs (UNDESA), available at http://www.johannesburgsummit.org/html/documents/backgrounddocs/icleisurvey2.pdf (accessed January 2005).

For population data: World Bank, World Development Indicators (WDI) 2004, http://www.worldbank.org/data/wdi2004/.

Variable #: 53 Code: CIVLIB

Description: Civil and Political Liberties

Freedom House, Freedom in the World, available in pdf at http://www.freedomhouse.org/research/freeworld/2003/averages.pdf (accessed January 2005).

Variable #: 54 Code: CSDMIS

Description: Percentage of variables missing from the CGSDI "Rio to Joburg Dashboard"

Consultative Group on Sustainable Development Indicators, Dashboard of Sustainability, "Rio to Joburg Dashboard," 2002, http://www.iisd.org/cgsdi/dashboard.asp (accessed January 2005), and Jochen Jesinghaus, personal communication, 9 January 2002.

Variable #: 55 Code: IUCN

Description: IUCN member organizations per million population

For membership data: IUCN-The World Conservation Union, http://www.iucn.org/members/Mem%20Statistics.htm (accessed January 2005);

For population data: World Bank, World Development Indicators 2004, http://www.worldbank.org/data/wdi2004/ (accessed

Variable #: 56 Code: KNWLDG

Description: Knowledge creation in environmental science, technology, and policy

Index based on data from Yale Center for Environmental Law and Policy, Knowledge Divide Project (Dr. Sylvia Karlsson, Tanja Srebotnjak, Patricia Gonzalez).

For covariates data: Research and Development (R&D) spending as % of GDP, Researchers per million people: World Bank, World Development Indicators 2003, http://www.worldbank.org/data/wdi2003/ (accessed January 2005), United Nations Educational, Scientific and Cultural Organization (UNESCO) Institute of Statistics for selected R&D indicators, May 2004, http://www.uis.unesco.org/-ev.php?ID=5180_201&ID2=DO_TOPIC (accessed January 2005); For GDP data: United Nations Statistics Division, Common Database, 2001 current GDP in USD, http://unstats.un.org/unsd/cdb/cdb_help/cdb_quick_start.asp (accessed January 2005); For Population data: World Bank, World Development Indicators 2003, http://www.worldbank.org/data/wdi2003/ (accessed January 2005).

Additional or updated country data as follows: Taiwan: Researchers per million inhabitants are based on figures from National Statistics Taiwan, the Republic of China, at http://www.dgbas.gov.tw/census~n/four/e4423.htm (accessed December 2004) using a rough factor of 1 in 10 professionals, scientific and technical services personnel is a researcher, R&D spending as percent of GDP, Taiwan Headlines citing data from the Directorate-General of Budget, Accounting & Statistics (DGBAS), http://www.taiwanheadlines.gov.tw/-20030402/20030402b3.html (accessed December 2004).

Variable #: 57 Code: POLITY

Description: Democracy measure

Polity IV Project "Political Regime Characteristics and Transitions", 1800-2002, Monty Marshall, University of Maryland, 2004, http://www.cidem.umd.edu/inser/polity/ (accessed January 2005).

Variable #: 58 Code: ENEFF

Description: Energy efficiency

For energy consumption data: US Energy Information Agency (EIA), http://www.eia.doe.gov/emeu/iea/wecbtu.html (accessed January 2005).

For GDP data: World Bank, World Development Indicators 2004, GDP in PPP, http://www.worldbank.org/data/wdi2004/ (accessed December 2004).

Additional country data as follows: Taiwan: US Energy Information Administration (EIA), E.1g World Energy Intensity (Total Primary Energy Consumption, Per Dollar of Gross Domestic Product), 1980-2002, http://www.eia.doe.gov/pub/international/iealf/tablee1.xls, B.2 World Gross Domestic Product at Market Exchange Rates, 1980-2002, http://www.eia.doe.gov/pub/international/iealf/tableb2.xls.

Variable #: 59 Code: RENPC

Description: Hydropower and renewable energy production as a percentage of total energy consumption

US Energy Information Agency, http://www.eia.doe.gov/emeu/iea/wecbtu.html (accessed January 2005).

Additional and updated country data as follows: Austria: Statistics Austria, for renewable energy, http://www.statistik.at/fachbereich_energie/neue_tab.shtml, for gross inland consumption, http://www.statistik.at/fachbereich_energie/gesamt_tab.shtml. Ireland: Sustainable Energy Ireland, National Energy Balances, www.sei.ie. Lithuania: Statistics Lithuania, Statistical Yearbook of Lithuania 2003. Mauritius: Central Statistics Office, Digest of Energy and Water Statistics, 2003, Table 4.1 and Table 3.3.

Variable #: 60 Code: DJSGI

Description: Dow Jones Sustainability Group Index (DJSGI)

Dow Jones SAM Sustainability Group, http://www.sustainability-index.com/htmle/djsi_world/members.html (accessed January 2005) and communication.

Variable #: 61 Code: ECOVAL

Description: Average Innovest EcoValue rating of firms headquarted in a country

Innovest Strategic Value Advisors, http://www.innovestgroup.com (communication).

Variable #: 62 Code: ISO14

Description: Number of ISO 14001 certified companies per billion dollars GDP (PPP)

For ISO14000/EMAS registered companies: Reinhard Peglau, c/o Federal Environmental Agency, Germany, http://www.ecology.or.jp/-isoworld/english/analy14k.htm (accessed December 2004).

For GDP (PPP) data: World Bank World Development Indicators 2004, http://www.worldbank.org/data/wdi2004/ (accessed November 2004), UNSD Common Database, GDP at market prices, current prices, US\$ (UN Estimates) for Andorra, Brunei Darussalam, Liechtenstein, Monaco, Myanmar, Puerto Rico, and Qatar, http://unstats.un.org/unsd/cdb/cdb_help/cdb_quick_start.asp (accessed January 2005).

Variable #:	63	Code:	WEFPRI
v at lable π .	05	Coue.	W LTT KI

Description: World Economic Forum Survey on private sector environmental

World Economic Forum (WEF) Survey, The Global Competitiveness Report 2003-2004, Porter, Michael E. et al, Oxford University Press, 2003-2004, http://www.weforum.org/site/knowledgenavigator.nsf/Content/KB+Country+Profiles (accessed January 2005).

Variable #: 64 Code: RESCARE

Description: Participation in the Responsible Care Program of the Chemical Manufacturer's Association

International Council of Chemical Associations (ICCA), Responsible Care Status Report 2002, Appendix 4, http://www.icca-chem.org/pdf/icca004.pdf (accessed January 2005).

Variable #:	65	Code:	INNOV

Description: Innovation Index

World Economic Forum, 2003-2004 Global Competitiveness Report, http://www.weforum.org/site/homepublic.nsf/Content/-Global+Competitiveness+Programme%5CGlobal+Competitiveness+Report (accessed January 2005).

Variable #: 66 Code: DAI

Description: Digital Access Index

Digital Access Index (DAI) of the International Telecommunication Union (ITU), http://www.itu.int/ITU-D/ict/dai/ (accessed December 2004)

Variable #: 67 Code: PECR

Description: Female primary education completion rate

United Nations Educational, Scientific and Cultural Organization (UNESCO), Institute for Statistics. Global Education Digest 2004 - Comparing Education Statistics Across the World. Montreal, 2004 accessed from the UNSD Millennium Indicator Database, http://millenniumindicators.un.org/unsd/mi/mi_series_xrxx.asp?row_id=745 (accessed January 2005), and the World Bank World Development Indicators 2004, http://www.worldbank.org/data/wdi2004/ (accessed January 2005).

Additional and updated country data as follows: Albania: Albanian Institute of Statistics, Annual Statistical Report of Education 2002-2003. Austria: Statistics Austria. Italy: Ministero dell'Istruzione, dell'Università e della Ricerca, http://www.miur.it/; and Istat Rapporto Annuale, 2003, http://www.sitat.it/. Lithuania: Statistics Lithuania, http://www.std.lt or Eurostat's website http://europa.eu.int/-comm/eurostat. Taiwan: Directorate General of Budget Accounting and Statistics, Socio-Economic Data of Taiwan, http://www.dgbasey.gov.tw/dgbas03/bs2/gender/n9111.htm. United Arab Emirates: Ministry of Education & Youth, Annual Statistical Report 2003. Zimbabwe: Central Statistical Office, Education Statistics in Zimbabwe.

Variable #: 68 Code: ENROL

Description: Gross tertiary enrollment rate

United Nations Educational, Scientific and Cultural Organization Institute for Statistics (UNESCO-UIS), http://www.uis.unesco.org/ev.php?URL_ID=5187&URL_DO=DO_TOPIC&URL_SECTION=201 (accessed January 2004).

Additional or updated country data as follows: Albania: Albanian Institute of Statistics, Annual Statistical report of Education 2002-2003. Austria: Statistics Austria, EU data collection (common data collection of UNESCO, OECD and EUROSTAT), school and university statistics. Finland: Statistics Finland, Statistical Yearbook 2003. Italy: Ministero dell'Istruzione, dell'Università e della Ricerca, http://www.miur.it/ and Istat "Università e Lavoro," http://www.istat.it/DATI/unilav2004/index.html. Lithuania: Statistics Lithuania, various publications at http://www.std.lt or http://europa.eu.int/comm/eurostat. Mauritius: Central Statistics Office, "Participation tertiary education/ Tertiary Education Commission, 2003". Taiwan: Ministry of Education, Taiwan, The international comparative indices for education, http://www.edu.tw/EDU_WEB/EDU_MGT/STATISTICS/EDU7220001/temp1/o verview.files/frame.htm?open. United Arab Emirates: Ministry of Education & Youth, Annual Statistical Report 2003. Zimbabwe: Central Statistical Office 2003, Zimbabwe.

Variable #: 69 Code: RESEARCH

Description: Number of researchers per million inhabitants

United Nations Economic, Scientific and Cultural Organization (UNESCO), Institute for Statistics, http://www.uis.unesco.org/ev.php?-ID=5180_201&ID2=DO_TOPIC (accessed January 2005). Data on Researchers per million inhabitants for Taiwan are based on figures from National Statistics Taiwan, the Republic of China, at http://www.dgbas.gov.tw/census~n/four/e4423.htm (accessed 30 December 2004) using a rough factor of 1 in 10 professionals, scientific and technical services personnel is a researcher.

Variable #: 70 Code: EIONUM

Description: Number of memberships in environmental intergovernmental organizations

Yearbook of International Organizations 2003/04. Electronic access by subscription through Union of International Associations, http://db.uia.org/scripts/sweb.dll/a?DD=OR (accessed January 2005). List of environmental intergovernmental organizations available at http://www.yale.edu/envirocenter/esifaq.htm.

Additional or updated country data as follows: Republic of Korea: Ministry of the Environment, Policy Coordination Division.

Variable #: 71 Code: FUNDING

Description: Contribution to international and bilateral funding of environmental projects and development aid

For aid data: Global Environmental Facility (GEF) contributions and receipts and Organisation for Economic Co-operation and Development (OECD) bilateral environmental aid;

For ancillary economic data (GNI, PPP, USD current income): World Bank, World Development Indicators 2004, http://www.worldbank.org/data/wdi2004/ (accessed November 2004);

For population data: CIA World Factbook, http://www.cia.gov/cia/publications/factbook/ (accessed November 2004).

Variable #: 72 Code: PARTICIP

Description: Participation in international environmental agreements

Membership information, national communications, and initiatives related to the following conventions: United Nations Framework Convention on Climate Change (UNFCCC) and Kyoto Protocol, http://www.unfccc.org (accessed October 2004), Vienna Convention on the Protection of the Ozone Layer and Montreal Protocol with amendments, http://www.unep.org/ozone/Treaties_and_Ratification/-2A_vienna%20convention.asp (accessed October 2004), Convention on the Trade in Endangered Species (CITES), http://www.cites.org (accessed October 2004), Basel Convention on the Transboundary Movement of Hazardous Waste, http://www.basel.int (accessed October 2004), United Nations Convention to Combat Desertification (UNCCD), http://www.unccd.int (accessed October 2004), United Nations Convention on Biological Diversity, http://www.biodiv.org (accessed October 2004), and The Ramsar Convention on Wetlands and the Cartagena Protocol http://www.ramsar.org/ (accessed October 2004). Variable #: 73 Code: CO2GDP

Description: Carbon emissions per million US dollars GDP

For CO2 emission data: Carbon Dioxide Information Analysis Center (CDIAC), http://cdiac.esd.ornl.gov/trends/emis/tre_coun.htm (accessed January 2005);

For GDP data: World Bank World Development Indicators 2004, GDP in constant 1995 US dollars, http://www.worldbank.org/data/wdi2004/ (accessed December 2004). Alternative GDP data as follows: Peoples Republic of Korea: from United Nations Statistics Division Common Database (UNCDB), GDP at market prices, current prices, USD for 2000 (UN Estimates), http://unstats.un.org/unsd/-cdb/cdb_help/cdb_quick_start.asp (accessed December 2004), Cuba, Libya, and Myanmar: CIA World Fact Book 2004 GDP USD (PPP), http://www.cia.gov/cia/publications/factbook/ (accessed December 2004).

Additional or updated country data as follows: Taiwan: CO2 data from CDIAC, http://cdiac.esd.ornl.gov/ftp/ndp030/nation00.ems, GDP data from US Energy Information Administration (EIA), B.2 World Gross Domestic Product at Market Exchange Rates, 1980-2002, http://www.eia.doe.gov/pub/international/iealf/tableb2.xls (in constant 1995 USD).

Variable #: 74 Code: CO2PC

Description: Carbon emissions per capita

<u>Carbon emissions per capita:</u> United Nations Statistics Division, Millennium Indicator Database, based on data from United Nations Framework Convention on Climate Change-United Nations Department of Economic and Social Affairs (UNFCCC-UNDESA), http://unstats.un.org/unsd/mi/mi_goals.asp (accessed January 2005).

Additional or updated country data as follows: Taiwan: CO2 data from Carbon Dioxide Information Analysis Center (CDIAC), http://cdiac.esd.ornl.gov/ftp/ndp030/nation00.ems, Population data from Ministry of the Interior, Taiwan Population Database, http://www.ris.gov.tw/ch4/static/st20-1.xls. Slovenia: CO2 and Population data from, UNFCCC, National Inventory Report.

Variable #: 75 Code: SO2EXP

Description: SO2 Exports

The Cooperative Programme for Monitoring and Evaluation of the Long-range Transmission of Air Pollutants in Europe Meteorological Synthesizing Centre West Status Report (EMEP_MSC-W) 2003, ISSN 0804-2446, http://webdab.emep.int/ (accessed January 2005), and US Committee for the International Institute for Applied Systems Analysis (IIASA) Regional Air Pollution Information and Simulation Europe (IIASA_RAINS_Europe), http://www.iiasa.ac.at/rains/Rains-online.html?sb=8 (accessed January 2005) and IIASA RAINS-Asia data from the 2002 ESI.

Variable #: 76 Code: POLEXP

Description: Import of polluting goods and raw materials as percentage of total imports of goods and services

United Nations Commodity Trade Statistics database (COMTRADE), Department of Economic and Social Affairs/ Statistics Division, available online at http://unstats.un.org/unsd/comtrade/ (accessed December 2004), World Bank World Development Indicators 2004 for Total Imports of Goods and Services in current 2002 USD.

2005 Environmental Sustainability Index

Benchmarking National Environmental Stewardship

Appendix D Component and Indicator Tables

This page is intentionally blank.

Component and Indicator Scores

This section provides tables that rank the 146 countries contained in the ESI according to the five components and the twenty-one indicators. These tables provide a more detailed view into comparative country positions than the overall ESI score.

The component scores are presented as standard normal percentiles, ranging from a theoretical low of 0 to a theoretical high of 100. The indicator scores are presented as averages of the constituent variable values. These variable values, as described in Appendix A, are in the form of z-scores, with zero indicating the mean, +1 and -1 representing one standard deviation above and below the mean, +2 and -2 representing two standard deviations above and below the mean, and so on. In a "normal," bell-shaped distribution 68 percent of the scores fall within one standard deviation of the mean, 95 percent within two standard deviations, and 99.7 percent within three standard deviations. The actual distributions vary among the ESI indicators and variables.

The tables appear in the following sequence (related indicators are grouped together):

Component:	Environmental Systems
Component:	Reducing Environmental Stresses
Component:	Reducing Human Vulnerability
Component:	Social and Institutional Capacity
Component:	Global Stewardship
Indicator:	Air Quality
Indicator:	Water Quantity
Indicator:	Water Quality
Indicator:	Biodiversity
Indicator:	Land
Indicator:	Reducing Air Pollution
Indicator:	Reducing Water Stress
Indicator:	Natural Resource Management
Indicator:	Reducing Ecosystem Stresses
Indicator:	Reducing Waste and Consumption Pressures
Indicator:	Reducing Population Growth
Indicator:	Basic Human Sustenance
Indicator:	Reducing Environment-Related Natural Disaster Vulnerability
Indicator:	Environmental Health
Indicator:	Science and Technology
Indicator:	Environmental Governance
Indicator:	Private Sector Responsiveness
Indicator:	Eco-Efficiency
Indicator:	Participation in International Collaborative Efforts
Indicator:	Greenhouse Gas Emissions
Indicator:	Reducing Transboundary Environmental Pressures

Appendix E ESI Values in Small States

This page is intentionally blank.

Appendix E – ESI Values in Small States

Five small states meet all but the size inclusion criteria for the ESI. As we discuss below, their size makes their environmental challenges fundamentally different from the rest of the countries in the index. We cannot impute missing values for these countries because including them with larger countries would generate inaccurate results. Therefore, we rely solely on available data. Nevertheless, individual scores can provide a starting point for small countries to benchmark their performance against each other as well as to use their indicator scores as a policy tool.

The architecture of the ESI, in which all indicator scores are calculated in relative terms and then averaged to generate the composite scores, presumes that the countries are fundamentally comparable. It also assumes that the significance of a very low or a very high score for any one variable is comparable across countries, and that it relates directly to practical concerns for environmental sustainability in each country.

For very small states this assumption is violated for several variables and indicators. This is especially true for the landscape and biodiversity related measures. The status of endangered species, for example, is problematic as a relative indicator. Many very small states are islands, which have different biodiversity constraints than other countries. For example, the 5,000 square kilometer cutoff for inclusion in the ESI is considered by the World Conservation Union (IUCN) to be the minimum habitat range for a species to avoid being on the Red List of threatened species.

In addition, the ESI architecture assumes that an environmentally sustainable country is one which generates the bulk of the most valuable environmental services - such as clean air, plentiful water, arable land, biodiversity, and so on - from internal resources. Yet for countries that are extremely small this assumption makes little sense. A country such as Singapore, for example, must rely on its neighbors for some environmental resources. Similarly, the ESI assumes that a sustainable country sets aside a significant portion of its land as protected wilderness. Yet in very small countries the relevance of this metric differs from that of other ESI countries and is not comparable.

Many indicators, however, are equally relevant in small and large countries. Air and Water Quality, the vulnerability measures, and most of the capacity measures easily translate to the small country context. Because many of the data sets in the ESI that are relevant for countries of any size are not available and cannot be plausibly imputed (see Table E.1), we only report available component scores for small countries excluded from the ESI. Comparisons to larger countries should be undertaken with caution for the reasons given above.

Country Name	ESI Score	SYSTEM	STRESS	VULNERABILITY	CAPACITY	GLOBAL
Mauritius	56.69	91.87	81.63	15.03	48.32	51.76
Luxembourg	49.56	40.93	13.95	34.06	57.85	85.46
Malta	47.13	40.93	76.93	13.15	49.85	50.94
Singapore	41.84	59.66	49.21	13.15	55.14	13.11
Barbados	*	85.04	85.82		44.79	20.11

Table E.1: Small States ESI Scores (based on available data – no imputations generated)

* We cannot calculate an ESI score for Barbados due to the lack of complete indicators in the vulnerability component.

Benchmarking National Environmental Stewardship

Appendix F Comparing the ESI with Other Sustainability Indicators

This page is intentionally blank.

Appendix F – Comparison of the ESI to Other Sustainability Indicators

ESI v. Ecological Footprint Index

The Ecological Footprint Index converts a country's total resource consumption into the equivalent of hectares of biologically productive land, and then divides this by population to obtain a final value of hectares per capita. Like the ESI, it is measured on the national level, but the two indices differ considerably in their methodology and scope. Given that the Footprint Index is included in the ESI's Reducing Waste and Consumption Pressures indicator, we expect to find a relationship between the two indices.

The correlation between the ESI and the Ecological Footprint explains approximately 15% of the variation in the ESI. The correlation between the two indices is negative, meaning that large footprints tend to coincide

with high ESI values. Since both indices measure certain aspects of sustainability, it may be surprising that high ESI scores are related to resource consumption.

One explanation for the inverse correlation is that the ESI covers a wider range of sustainability issues than the Ecological Footprint including Environmental Systems, and Socioinstitutional Capacity indicators, as well as measures of International Environmental Collaboration and Stewardship. High levels of resource consumption are clearly not sustainable over the long-term. However, countries with small footprints are not necessarily sustainable either. If their footprints are small because of a lack of economic activity and pervasive poverty, their situation cannot be

held out as a policy aspiration. Rich countries with larger footprints tend to have lower human vulnerability and higher capacity values, meaning that they are better equipped to deal with environmental pollution and the resulting health, ecological, and economic impacts. Countries with both large footprints and high capacity can therefore invest in reducing pollution stresses, and address but not negate, their high natural resource consumption rates.

Environmental Vulnerability Index

Environmental vulnerability includes susceptibility to natural hazards, sea-level rise, natural resource depletion, fragile ecosystems, and geographical isolation. Although low vulnerability is not completely parallel with sustainability, high environmental vulnerability creates a variety of impediments to sustainable development. The South Pacific Applied Geoscience Commission (SOPAC), in collaboration with the United Nations Environment Programme (UNEP) and others, has developed an Environmental Vulnerability Index (EVI) to measure vulnerability. The Index aims to provide a sense of the environmental conditions that predispose a country to internal and external shocks that adversely impact its physical entities (people, buildings, ecosystems), economy, and wellbeing.

A weak relationship was found between the ESI and the EVI, and no significant trend could be detected. Based on different conceptual foundations, the EVI and ESI clearly gauge different aspects of environmental sustainability. High environmental vulnerability reduces a country's capacity to address other issues such as reducing environmental stresses and improving natural resource use efficiency. These issues are included in the ESI but are not at the heart of the EVI.

 Table F.1: Correlations Between 2005 ESI Components and Other Indices

* statistically significant at 0.05 level ** statistically significant at 0.01 level *** statistically significant at <0.01 level

Note: High ESI scores correspond to higher environmental sustainability, but Ecological Footprint and EVI scores correspond to high resource consumption and vulnerability, respectively.

Table F.1 shows how and why the ESI and comparative indices diverge. The Ecological Footprint, for example, is a measure primarily of environmental pressure, especially consumption pressure, with no overt effort to balance pressure measures with systems, impact or capacity measures. Therefore the Footprint has a strong correlation with the ESI Waste and Consumption indicator. Interestingly, its highest positive correlation is with the Science and Technology indicator, which reflects the fact that developed countries with high per capita incomes tend to have strong scientific and technological sectors as well as high resource use intensities. The Environmental Vulnerability Index is an index of states and pressures, as shown in the systematically high correlation with the ESI Systems and Stress indicators. The lower correlation levels with the ESI human impact, capacity, and global stewardship measures reflect the different scopes and purposes of these indices.

Millennium Development Goal 7

In September 2000, 189 nations adopted the United Nations Millennium Declaration, committing themselves to a series of "Millennium Development Goals" to alleviate poverty and promote sustainable development. The United Nations Secretariat and its specialized agencies and programs, as well as representatives of IMF, the World Bank, and OECD have defined 8 goals, 18 targets and 48 indicators to measure progress towards the Millennium Development goals. Among the eight goals, Goal 7 is to ensure environmental sustainability.

Goal 7 includes three targets and eight indicators but for two of them, sufficient data are currently not available. The indicators included in this analysis are: Proportion of land area covered by forest (FAO), Ratio of area protected to maintain biological diversity to surface area (UNEP-WCMC), Energy use (kg oil equivalent) per \$1 GDP (PPP) (IEA, World Bank), Carbon dioxide emissions per capita (UNFCCC, UNSD), Consumption of ozone-depleting CFCs (ODP tons) (UNEP-Ozone Secretariat), Proportion of population with sustainable access to an improved water source, and Proportion of population with access to improved sanitation.

In an experimental analysis, we attempt to create an index based on the six available MDG Goal 7 indicators. We can then compare the performance of countries on both the MDG Goal 7 index and the ESI in order to identify interesting similarities or differences between the two measures. To create the MDG Goal 7 index, we first apply principal component analysis and use the resulting principal components and factor loadings to transform the original data into a single index. The initial PCA suggests keeping three principal components (see Table F.2).

The first principal component is most highly correlated with Carbon dioxide emissions per capita, Proportion of the population with sustainable access to an improved water source, and the Proportion of population with access to improved sanitation. The second component correlates with Protected area ratio to surface area, while the third is most highly correlated with the Proportion of land area covered by forest.

For the final index, we calculate the principal component scores for the selected principal components and add these values together for every country. We then regress the ESI on the new MDG Goal 7 index. The result is a strong positive correlation between the two indices, as shown in Figure F.3. Nearly 30% of the ESI variation is explained by the MDG Goal 7 index. However, we note that the MDG Goal 7 index could only be calculated for 56 countries due to missing data, and the interpretation of the strong relationship is therefore restricted to this set of countries. The list of countries is shown in Table F.3.

		Initial Eigenv	values	Extraction Sums of Squared Loadings			
Component	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	
1	2.2	31.7	31.9	2.2	31.7	31.7

11	Cameroon	30	Jordan	49	Tunisia
12	Dem. Rep. Congo	31	Kazakhstan	50	Tanzania
13	Colombia	32	Kenya	51	United States
14	Costa Rica	33	South Korea	52	Venezuela
15	Dominican Rep.	34	Sri Lanka	53	Viet Nam
16	Algeria	35	Mexico	54	South Africa
17	Ecuador	36	Myanmar	55	Zambia
18	Egypt	37	Niger	56	Zimbabwe
19	Ethiopia	38	Oman		

Figure F.3 suggests that countries with similar scores on the MDG Goal 7 index, experience a range of environmental conditions. For example, while Brazil and South Korea both have high MDG scores, Brazil performs much better on the ESI. South Korea, Saudi Arabia and other countries have relatively high MDG index values because they succeed in providing the basic human services measured by MDG Goal 7 index. However, these countries fail to perform well on several of the dimensions covered by the ESI, including Environmental Systems and Reducing Environmental Stresses.

Developing countries such as Pakistan and Zimbabwe have low CO_2 emissions, and CFC consumption, which contribute to high MDG Goal 7 index scores, but also have low Capacity and high Human Vulnerability scores, which reduce their ESI values. The results suggest that measuring basic human needs such as water supply and sanitation, combined with a narrow set of proxies for sustainable resource as done in MGD 7, is not sufficient to track the broader set of environmental sustainability issues that are measured by the ESI.

2005 Environmental Sustainability Index

Benchmarking National Environmental Stewardship

Appendix G An Ideal Set of ESI Indicators

This page is intentionally blank.

Appendix G – An Ideal Set of ESI Indicators

Ideally, a measure of environmental sustainability would encompass a range of issues broad enough to permit a complete appraisal of each country's environmental state. In this Appendix, we briefly review what we think a complete ESI would include, and discuss the constraints that prevent us from achieving such an ideal.

Systems

An ideal set of systems measures would span both natural and managed environmental systems, and cover the full range of terrestrial, atmospheric, and aquatic systems, In particular, such a set of indicators would include the following:

- Cultivated systems, including measures of soil fertility and soil moisture, pest management practices, genetic diversity, and crop yields. Only crop yields are actually available, and in the absence of measurements of the agricultural practices underlying them, they are not suitable as a sustainability measure.
- Managed forests, including measures of the quality of forests (genetic stock, tree circumference, resistance to pests and disease, and so on) and the nature of forestry practices. These measures are not available on a comparable basis across countries.
- Fisheries, including measures of the size, health, and age structure of the relevant population stocks as well as the management practices applied. This area has very little comparable information available.
- Water quantity, including measures of the availability of surface freshwater as well as groundwater. In many countries freshwater volumes can be estimated reasonably well, though there is unevenness in how this is carried out. Paradoxically, the number of stream gauges is declining even as human inter-

vention in the hydrosphere is increasing. Groundwater availability is also very poorly measured.

- Water quality, including measures of eutrophication, turbidity, dissolved oxygen, and other critical indicators. There are two main deficiencies of the available measures in this regard. First, very few countries report water quality data to an international body. Second, it is difficult to make the available measures comparable because of natural variation in baseline levels of these measures. Some river basins are naturally turbid; others are not. A high turbidity level in the first kind of river is not a sign of low sustainability, while it is such a sign in the second.
- Air quality, including measures of pollutants such as sulfur dioxide, nitrogen oxides, particulates, volatile organic compounds (VOCs), and ozone. Few countries collect these measures in a comparable way, and those that do, report data for only a handful of urban areas. Tragically, one of the most serious and widespread forms of air pollution, concentration of indoor particulates from solid fuel combustion in the home, is not measured at all except in isolated, ad hoc efforts or through proxies.
- Landscape, including measures of urbanization, deforestation, agricultural conversion, and other anthropogenic alterations of the land. Of these, deforestation has received the most effort, and there are rough measures of the others.
- Biodiversity, including measures of both genetic and organismic diversity as well as of preservation of critical habitat and fragmentation of ecosystems. There are virtually no accepted measures of these phenomena that are comparable across nations.

• Sensitive ecosystems, including measures of coastal, mountain and dryland ecosystem health. These ecosystems are either under high stress or experience high vulnerability, and they would best be measured using indicators tailored to their special circumstances. However, no systematic, comparable measures have been collected.

Stresses

Within the Stresses component, we would like to be able to measure the full range of pressures on environmental systems including:

- Air pollution emissions, including emissions of the criteria air pollutants sulfur dioxide, nitrogen oxides, and volatile organic compounds (VOC). Many countries measure such emissions, and estimates are widely available.
- Water pollution, including measures of eutrophying and toxic chemicals released into watersheds, and untreated sewage. There are few comparable measures of such pollution, although there are proxies.
- Water consumption, including measures of surface and groundwater withdrawals in comparison to their recharge rates. There are reasonable estimates of surface water consumption, though groundwater use is unevenly measured, especially in comparison to recharge rates.
- Stresses on ecosystem functioning, including measures of anthropogenic disturbances to aquatic, terrestrial, and marine ecosystems. There are few comparable measures that fall into this category, though Europe has developed an effective system to measure the extent of acidification of land and aquatic ecosystems, and there are global efforts to quantify deforestation. There are no similar efforts to quantify disturbances to the hydrosphere or the coastal and marine environments
- Waste and consumption, including measures of solid waste generation, land-fill volume, hazardous waste generation, unsafe disposal of waste, and natural re-

source consumption relative to carrying capacities broadly conceived. There are no adequate, comparable measures of these issues, although the work undertaken by those producing the Ecological Footprint Index (Wackernagel and colleagues) has made it possible to quantify natural resource consumption much more effectively than before.

- Releases of toxins, carcinogens, endocrine disruptors and other known or potentially hazardous chemicals. There are no international programs to collect such information on a comparable basis, with the exception of a few targets of international regulation such as persistent organic pollutants (POPs).
- Soil degradation, including measures of salinization, nutrient depletion, and desertification. There are no national comparable measures of this phenomenon that are considered reliable by soil experts.
- Population, including measures of fertility and total growth. This is well measured.

Human Vulnerability

Within the Human Vulnerability component, we would like to measure the following:

- Food security, including measures of caloric intake, malnutrition, and susceptibility to famine or other shortfalls in food availability. People who are malnourished are more susceptible to pollution harms as well as more vulnerable to resource mismanagement.
- Environmental health, including measures of morbidity and mortality stemming from waterborne vectors, such as intestinal infectious diseases; from poor air quality, such as respiratory diseases; and from exposure to toxins and mutagens, such as some cancers. In practice our ability to create such measures is severely limited. The World Health Organizations' pathbreaking work on the environmental burden of disease was not able to quantify such outcomes at a national level, but only within large global regions.

- Susceptibility to environmentally-related natural disasters, such as floods, droughts, landslides and hurricanes. In the past it has been hard to create comparable metrics on this dimension, but the situation has improved due to intense international work in recent years.
- Economic security, including measures of environmentally-induced poverty traps and economic losses from broad environmental change. There are no comparable data on this dimension of human vulnerability, although recent breakthroughs in the methodologies associated with environmental accounting hold promise for improvements in the future.

Social and Institutional Capacity

Within the Social and Institutional Capacity component, the ideal indicators are as follows:

- Environmental governance, including measures of the effectiveness of the environmental regulatory apparatus, the flexibility and innovativeness of the regulatory regime, the strictness of enforcement of environmental laws as well as the extent of endemic problems such as corruption or deviation from rule of law, the use of best practices concernmonitoring, assessment, ing and implementation, the extent of public participation in environmental decisionmaking, and the availability of environmental information. In practice there are few good measures specific to the environment, though there are some more generic governance measures that are relevant.
- Science and Technology, including measures of the level of environmental knowledge among the public, the capacity of a society to respond to technical challenges, and the ability of a society to innovate and generate less-environmentally harmful products and production processes over time.
- Private Sector Responsiveness to Environmental Challenges, including measures of private sector compliance with laws,

commitment to environmental stewardship, and capacity for environment-related innovation. The private sector is central to overcoming pollution control and natural resource management challenges, therefore measures of these would be of great value.

• Eco-Efficiency. While absolute levels of pollution and energy use matter, one key gauge of a society's environmental trajectory is its resource productivity as measured by energy use/GDP and other metrics of resources conserved per unit of economic output.

Global Stewardship

Within the Global Stewardship component, the ideal indicators are as follows:

- Greenhouse Gas Emissions. Because climate change is such an important global environmental issue, measuring the degree to which countries are contributing to the problem is vital within this category. Indeed, it is important to track emissions both as a function of economic scale (measuring efficiency) and population (measuring absolute impacts).
- Participation in international collabora-• tion. There are hundreds of international environmental agreements, and ideally we would be able to construct a measure that fairly evaluates the participation of countries across a number of agreements. However, in practice this is difficult to accomplish as the number of agreements varies considerably across world regions and some countries have fewer opportunities to participate based solely on their location. In addition, the easiest things to measure (signature and ratification rates; compliance with reporting requirements; and so on) are seldom the most important. More meaningful measures would include adjustments of policies to achieve international goals; implementation of monitoring and research programs to further international efforts; and other substantive actions.

- Transboundary environmental pressures. Pollutants can flow across borders, and in some cases constitute a significant portion of total pollution within a receiving country. Such transboundary spillovers can be an important source of air pollution, water pollution, and hazardous chemicals. In addition, upstream countries are capable of withdrawing water in sufficient quantities to seriously deplete available water in downstream countries. A country can also significantly diminish the ability of migratory species to survive through alteration of habitat or other pressures. In practice, very few of these transboundary pressures are measured. Flows of air pollution in Europe are extremely well monitored. Acid rain spillovers in Asia have been modeled by the World Bank, but these data are an exception.
- Environmental impacts of trade, investment and consumption flows. In addition to generating direct environmental harm outside their borders, countries can potentially exert profound indirect effects through their international economic activities. These are some of the least understood or measured impacts. Although the economic flows are monitored

quite closely, their environmental impacts are not. The task is made more complicated because most economic flows have both positive and negative effects, and because the effects are seldom uniform across different locations. Monitoring efforts that link specific environmental outcomes in one location to the economic flows originating in another could produce large improvements in this area. All of the available proxies are admittedly crude.

Conclusion

Conceptually, environmental sustainability involves a wide range of issues, many of which are hard to quantify accurately and appropriately using available data sources. In general, metrics tend to be closely linked to human activities or human impacts. The pollution measures, capacity measures, and human welfare measures, for example, tend to be more accurate and easily available than the others. The ecosystem measures tend to be the least covered, with entire broad categories remaining chiefly a blank slate almost twenty years after the Brundtland Report.

2005 Environmental Sustainability Index

Benchmarking National Environmental Stewardship

Appendix H Critiques and Responses

This page is intentionally blank.

Appendix H – Critiques and Responses

Earlier versions of the ESI received widespread media attention, favorable reviews in the academic literature (see Appendix I) and positive reception by many countries. As with any novel approach to a complex set of issues, it has also been subject to criticism. In this Appendix, we discuss the core critiques of the previous ESI releases that are especially pertinent to the 2005 edition.

Critique:

The ESI underemphasizes certain critical aspects of environmental sustainability, such as climate change, and the equal weighting of the ESI is arbitrary and/or inappropriate.

Response:

The ESI refrains from placing high weights on a small number of factors because we think the environmental sustainability agenda is appropriately broad, and we wish our index to be faithful to that agenda. It would be irresponsible to try to reduce a measurement of environmental responsibility to a small handful of metrics. The word "environment" refers to a wide range of issues including air and water pollution, waste management, toxic exposures, as well as range of natural resource management issues. We recognize that the equal weighting across the 21 indicators of the ESI is somewhat arbitrary. However, as discussed in Appendix A, neither expert evaluation nor statistical analysis produced divergent weights. We therefore do not see any viable alternative to equal weighting. And we note that virtually all efforts to aggregate indicators of this sort end up assigning equal weights.

Putting special emphasis on climate would suit the political agendas of some countries and some environmental NGOs. But it would not reflect the balance of environmental issues that countries across the world must address. Issues related to climate change are found in seven ESI variables, driving, in part, five different indicators. We think this is a balanced and appropriate level of focus on climate change.

Critique:

It is difficult to determine the implicit weights behind different areas of policy interest, such as climate change or biodiversity.

Response:

This critique is similar to the one above. As mentioned in Chapter 2, the ESI is based upon an unweighted average of the 21 indicators. This means that individual variable weights vary in their contribution to the overall ESI score in proportion to the number of variables in a given indicator – from a 2% contribution to the ESI score for indicators with only two variables to a 0.3% contribution for the Environmental Governance indicator with 12 variables. Given that all variables are conceptually related to the indicator in which they are placed (and indeed many variables represent different ways of measuring the same thing), we do not feel the implicit weights are a problem. Yet, we also recognize the value of having a fuller picture of the implicit weights of different issues of concern - such as air quality or biodiversity conservation. Thus, as a partial response to this critique, we offer here a table of the implicit weights of different policy realms included in the ESI based on an aggregation of the implicit weight of individual variables.

Table H.1: Relative Weights Given to	
Environmental Sectoral Issues	

Policy realms	Percent weight
Human Health Related	34.9
Water Related	18.3
Climate Change Related	17.3
Land Related	16.6
Air Pollution Related	11.9
Biodiversity Related	10.5
Energy Related	9.8
Toxics/Waste Related	4.9

(Issue areas overlap so percents do not add up to 100)

This is an approximate estimate of the relative weight apportioned to different issues based on a coding of variables by issue. Generic governance or science and technology variables were generally not attributed to any sector. Human health has a high weight in part because of the many variables that are relevant to human health and wellbeing.

Critique:

Environmental sustainability cannot be summarized in a single index. The index combines too many disparate elements in one thus rendering it meaningless.

Response:

There has been an undue focus on the aggregate ESI scores, which we consider to be indicative and not definitive. The rankings are only indicative of a country's relative place on a sustainability ladder built from the ESI variables and indicators. We have always sought to emphasize the indicators, and we have provided country profiles that clearly compare each country's performance relative to its income peer group for each of the 21 indicators. That said, if a country is performing well on all or most of the 21 indicators, it will yield a higher ESI score, reflecting its high performance on the component parts.

Critique:

Many countries that score highly on the ESI, such as the Nordic countries, have per capita levels of natural resource use beyond what the biosphere can sustain indefinitely (Wackernagel 2001).

Response:

While there may be an element of truth in this critique, we would argue just as strongly that a country with very low levels of consumption yet with high levels of under-five mortality due to poor air and water quality, lax environmental regulations, corruption and absence of civil and political liberties, is also environmentally unsustainable. There is a general predisposition in the environmental community (particularly in the developed world) to view environmental outcomes that are harmful to human health as somehow less important that aggregate consumption impacts on the global commons. The fact remains that if the local atmosphere and water bodies are heavily polluted, a country can hardly be deemed to be on the path to environmental sustainability. As noted above, the environmental literature ranges across many issues – and the ESI tries to capture this full range of policy challenges.

Environmental policymakers are furthermore expected to address a broad array of pollution control and natural resource management issues. An ESI that focused solely on resource depletion rates would be much less useful in this context. Finally, resource depletion projections are notoriously unreliable and inattentive to the dynamic world in which we live.

Critique:

Other indicators such as the Ecological Footprint do a better job of measuring what really matters – the impact of human resource consumption on the environment and the ability of human activity to be sustained in the biosphere.

Response:

We support all indicator initiatives, and expect that the policy community will naturally migrate to those they find most useful. We see a value in measuring consumption or natural resources. Indeed, we include the Ecological Footprint as a measure of consumption pressure within the ESI. But we are convinced that reducing environmental sustainability to a uni-dimensional measure of the hectares of biologically productive land needed to support an economy is inadequate. Sustainability is inescapably a multi-faceted concept that must encompass a range of ecological and environmental public health values.

Critique:

The ESI downplays or ignores transboundary or spillover effects of northern country's unsustainable consumption. It is designed to make dirty countries look clean (Morse and Fraser forthcoming).

Response:

The ESI has always included measures that assess a country's transboundary impacts. In 2001, we included an indicator on "protecting international commons" that included measures such as current CO₂ emissions, historical cumulative CO₂ emissions, CFC consumption and the ecological footprint deficit. In 2002 we created a separate greenhouse gas emissions indicator and retained an indicator for transboundary environmental pressures, but added variables that measured SO₂ exports and impacts on marine fisheries. In this ESI, we have added a variable to account for another dimension of cross-border effects on the environment – the import of polluting goods and raw materials as percentage of total imports of goods and services (or conversely, the export of polluting industries to other countries). It is true that the ESI puts greater weight on a country's efforts to enhance sustainability within its own borders, but it can hardly be said that we have ignored transboundary impacts.

Critique:

The ESI gives undue weight to intentions versus actual performance.

Response:

We acknowledge that active participation in multilateral environmental agreements or funding mechanisms is no substitute for onthe-ground environmental protection. In fact, in 2002 we produced an Environmental Performance Index that, for 22 OECD nations with richer environmental data, ranked countries according to performance and recent trends on air and water quality, protection of land resources, and climate change. Nevertheless, it is our perception that intentions do matter, and that becoming a party and providregular reports to environmental ing conventions is a reflection of a government's commitment to address important issues such as biodiversity loss and climate change.

Critique:

The ESI has been criticized for the lack of a causal model linked to an observable outcome.

Response:

Environmental sustainability is defined as the ability to maintain valued environmental assets over the next several decades and to manage problems that emerge from changing environmental conditions. Because the concept includes the future as well as the past and the present, we are hampered in creating a casual model linked to observable outcomes. In addition, environmental sustainability encompasses too many issues and is too broad in scope to permit a realistic causal model.

Economic growth models, in contrast, focus on a fairly narrow measure of economic output, such as changes in Gross Domestic Product (GDP). It is the extremely narrow formulation of the outcome that permits such inputs to be aggregated with precision. While similar precision cannot be achieved in the realm of environmental sustainability, it does not negate the need for attention to the range of issues in pollution control and natural resource management. The ESI and its underlying indicators offer a valid if approximate gauge of the diverse and growing environmental stewardship concerns.

Critique:

Measuring relative performance is meaningless if all countries are essentially on unsustainable trajectories.

Response:

It is true that no country appears to be on a truly sustainable path. But relative performance is nevertheless an important thing to measure. The Ecosystem Wellbeing Index sought to create absolute performance benchmarks, yet the benchmarks were largely arbitrary and had slim empirical underpinnings. Policy context is what matters to policy makers. Seeing what others have achieved is critical to understanding what is possible. Determining the leaders is essential if one is to identify "best practices." Decades of production of the Human Development Index show that developing country leaders genuinely care about their ranking. Laggards are powerfully motivated by their poor rankings (Esty 2002). Our interactions with a number of countries show that some are making efforts to improve performance on ESI indicators in an effort to raise overall ESI scores. We see no evidence that policy makers are making the same effort to reduce their country's ecological footprints or increase their wellbeing indices.

Critique:

The ESI has an inherently "northern" bias. It favors developed countries by including too many measures of capacity and favoring technological innovation over indigenous or local knowledge. development and those of underdevelopment. The ESI team has consistently sought the views and welcomed the critiques of southern colleagues as well as those who claim to represent the global South. Furthermore, if the ESI does have such a bias, it is certainly not evident in developing country performance, since 11 of the top 20 countries in the 2002 ESI were developing or transitional economies. The reality is that many measures that one might wish to include are simply not available. There are no internationally comparative data sets that measure indigenous knowledge.

Response:

The ESI attempts to measure in a balanced way both the environmental challenges of
